You would be violating copyright but if someone
sent it to you offline, who is going to know?
If you contact the copyright owner they might be
able to help you.

Yep, you're right. I don't want to explicitly nor inadvertently violate copyright. That's why I'd seek AMQRP's authorization before doing anything like this.

I wouldn't trust it. Sometimes the cure could
generate
a large amount of heat.

Now one might try the kind of Cyanoacrylate that is
deemed safe for use on foam. A lot of indoor R/C
modelers build models out of foam board. If their
superglues generated heat, they would be worthless.
I think to only 100% safe glue would be a water based
glue or not use any glue at all. Hot glues I would
still worry about the insulation melting though one
might get away with it.

You know, I just got in trouble on another list when a member requested, on list, that the contents and value of a package sent to them be misrepresented to avoid customs charges. I expressed dismay not only at the attempt at dishonesty, but the fact it was done on a public forum as well. I received copious hate mail for my criticism of this.

Now I see "who is going to know?" about a proposed copyright violation.

Has Ham Radio really deteriorated this much?

Fell asleep at the switch and missed the first run. Saw that Steve was starting a second run and ran to the post office.

To my delight the packet arrived today. Unfortunately I won't have time for the next week and a half to build it (leaving on a trip). When I get back I'll build my ATS3B then unpack my luggage.

Thanks Steve

From: Jim Fraser
Topic: 1687 Message: 1715

Well, I started building last night. I placed the identifying resistors on the band modules. And on the main board I installed the MPU (U6) and the DDS (U7). The DDS has three solder bridges I need to fix as it was getting late and I decided to stop. The DDS chip was not really too bad if careful, there were just a couple times where I though...just a little bit more solder...then the bridge appears!

After most of the ICs are in I will go back and follow the sequence in the manual. Concurrently I will also try to complete one band module every other evening. It will take some time to complete as I take my time carefully lining up parts so that it looks neat. I am in no big rush, besides the bands are pretty lousy anyway.

If you absolutely want to tack the ends down, I
believe a two part epoxy would be safe. Takes time or
use the
5 minute stuff. No heat.

Come on,

If one can find the copyright owner and they can
help
them, then fine. By all means, do it legally. If the
guy just really has to have the disk and he can't find

a source, then what's the big stink? This is just a
lousy CD. I suspect if the fellow can find the
copyright holder, I bet he might sell it to him no or
perhaps the person might be so honored, he might get

it for free or reduced cost.

Sending new stuff overseas is another issue.
Sending
used equipment is subject to depreciation as far as
tariffs are concerned.

Spectrogram is one. You can find the last freeware version on the site of Tom Hammond, N0SS. (Just Google his callsign) Many builders use that program to align the filters in the Elecraft K2.

Another option is the free PSK program Digipan.

There's a lot of free audio programs out there.

A good place to check the 3.5V is at the reference oscillator. 5 volts shows up in a lot of places, like pin 8 of U1, U2, ect. Or at the filter cap near the regulator. You just don't want to do it at the regulator, as if the probe slips and you short the input to the output, it will do some damage!

Nah Johnathan. I doubt you are the only one to wonder about this stuff. My ATS-3b has arrived but I am waiting for the solder paste from Cash Olsen before attempting to do anything with it. I took a close look at the parts and I have to admit that I approach this build with great trepidation. I only hope my knowledge of radio basics is going to be sufficient to get me through the trouble shooting as I fully expect that there will be issues for me to deal with, not the least of which will be my inability to see adequately to do the assembly.

Just keep asking the questions. I have no doubt that they and the answers will be of great use to me.

Time sure does move on doesn't it Bill. I first built a heathkit HW-101 some 35 years - 40 years ago..... And marveled that it all worked. and here today, other than for the higher power of the Heathkit and the SSB capabilities we have a tiny rig with as many bands that will fit in the space occupied by the 2 final tubes of the Heathkit (6146's I believe) with features that were only dreamt of back then. I 'll get the ATS-3b built. Question in my mind is, will I get it to work? HI

Still waiting for that solder paste.

I wasn't planning to put it in an Altoids style box, figuring that more room would be better but after seeing it and eyeing a "Fishermans Friend" box which I believe is identical to the Altoids, I'm thinking I may just go ahead. How neat to have such a multi-featured little rig in such a small container and the label/artwork on the Fishermans Friend box somehow seems more then appropriate. I may have to sit in the bathtub to build it in case I drop something but I'll be giving it a try.

1728. U4 upside down. Be careful.

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-09-30 13:17:49 UTC
From: kc7fys
Topic: 1728 Message: 1728

Ha! I found the varmint. U4 was in upside down. The instructions state that the print will be 'upside down,' but I had the jacks on the right, so my PCB was downside up! D'oh.
But when I fixed it--JOY on powerup. De-soldered and re-soldered pretty easily using hot air and a rolled up piece of beer can to focus the heat. Movin' forward!

I posted a photo of my candle warmer hot plate with heat spreader in the Photos section of this site - please see my previous post on this tool.

The 1/4" plate doesn't sit right top of the plastic ring around the candle warmer, even though it looks that way in the picture. Another aluminum plate .127" thick lies between the heater element's flat surface and the 1/4" aluminum heat spreader visible in the photo. They are held together by gravity.

My solution was far less elegant, but I found the plate IS big enough
if you remove the top half of the housing.

1732. another ATS-3B (almost) complete

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-01 03:15:03 UTC
From: John Shadle
Topic: 1732 Message: 1732

Alright, so I still have to wind a bunch of toroids and finish the 6 band modules, but I'm finished with the main board. Woohoo!

I powered up a few minutes ago and received the "8" message. In my excitement, I unplugged the radio and urged my wife to put the headphones in her ears to hear it, too; however, most likely due to the short power on/off switch I got "E" instead. Things are fine now, though.

Steve, this truly was a fun kit to build. It was just the right amount of challenging (a somewhat experienced kit-builder with only two other small SMD kits under my belt) and very rewarding.

I've put some photos up on flickr.com for you all to enjoy. Hope you have a chance to check them out.

http://flickr.com/photos/shadle/sets/72157602215143718/

For those of you who don't want to check out the photos or were just generally interested, here is the order in which I completed the build.

1. resistors
2. ICs
3. caps, inductors
4. through-hole parts

Seemed to work well for me.

Take care and good night.

To raise the hot plate above the plastic trim, I unscrewed the screws, separated the two halves, popped the hot plate out of the top half, pushed the hot plate through the hole in the top half (without bending the hot plate), then used some high-temperature RTV silicone sealant around the perimeter of the bottom of the hot plate to glue it to the top of the top housing, centered around the hole. Then, I reattached the bottom half using the original screws. Now, nothing protrudes above the surface of the hot plate itself. I don't have an AT Sprint board yet, so I don't know if the hot plate is big enough, but it has a diameter of about 3 7/8" (98 mm).

Ross,

This sounds like a great way to improve the candle warmer. Mine was slightly smaller and wouldn't heat the entire board, so I decided on the heat spreading plate. I did open it up and thought about modifying it, but I decided that even heat was important, and the surface on mine looks pretty thin - so I decided to test the spreaders, and before I knew it, I was there.

The 1/4" spreader takes a long time to come up to full temperature, so it isn't ideal - maybe 1/8" or less would be a better compromise, since it's already on top of another 1/8" piece of aluminum.

I tried unsoldering some SMT parts on some scrap 2-sided unetched copperclad board, using my modified candle warmer and plates, and it only took 20 or 30 seconds with the embossing hot air tool at about 2" before the solder melted. I decided that I need more practice, so I went ahead and ordered some solder paste from Cash Olson along with a SMT dummy load kit from Norcal. If the dummy load goes well, I'm planning to solder msot of the ATS-3B with the reflow method.

I haven't decided whether to try to do both sides this way. The Norcal dummy load is two-sided, so it will be a good test.

Comments from people who have tried doing both sides with the warmer and hot air tool would be appreciated!

Hi All,

I have the main board of my ATS-3B about 99% complete and thought I'd take a break and do a couple filter boards (15m and 17m) for the inital power up test. Those 0603 resistors sure are tiny, lost one and also lost an 0805 capacitor! Fortunately a local electronic parts house carries surface mount devices and I was able to pick up replacements without bugging Steve.

Regarding the toroids, those of you who have built the 3B or earlier models, did you wind the toroids with the turns close-wound or spread out around the core? Which way would maximize the power output?

Thanks in advance,
Jim K6JF

Scrunching LF1 decreases power. Scrunching LF2
increases power.

Wind them spread out so that you can scrunch them.

I ended up not going with the turn values or C3F
values in the manual. I used something more like the
last ATS3A version filters. I get 2.5/2.6 watts with 9
volts and 4.5/4.6 watts with 12 volts. This is for
80/40/30/20, haven't built 17 or 15 yet, but will
probably modify those as well.

Dave/wa3off has done some good work on the filter
boards, he should chime in too.

> increases power.

This probably depends on which module you are working with and whether or not you alter the turns count or caps values. That statement applied to my 40M module but my 80M module was the opposite, I think. More accurately, I think, is that scrunching the turns together increases the inductance. If you treat it like a matching network, it's a bit like tuning an antenna tuner. So far I've observed that scrunching both LF1 and LF2 may produce little change in output power while scrunching one and unscrunching the other seems to have more effect.

The way I have the filters operating, they seem to be transforming the 50 ohm antenna impedance down to about 17 ohms that the PA transistors see.

Pushing the output to 5W using 12V will definitely result in tripping the Tx overcurrent protection on occasion. Steve will probably hate me for saying it, but I ended up bumping the current limit up by 50% in my 3B so that it would be tolerant of slight mismatches during the antenna tuning process. At the unmodified current limit, there were times that I was tripping it even when operating the rig on only 8V with about 2W of output (when the untuned tuner was presenting a low impedance to the rig). Being an auto tuner, it will not adjust without a few seconds of output from the rig; with the original limit I had to switch to my ATS-3A for a signal to get the tuning cycle completed. Using a manual tuner like one of Steve's designs probably would not give as much difficulty.

Jim,

For my ATS-3A, I changed a few of the components a little bit, just to get a bit more output. Scrunching or separating turns may be all you need to do. Adding or subracting associated capacitance also may be useful to maximize output. Be sure to watch the supply current, because just maximizing the output isn't good if efficiency goes down too much.

Your results may depend on whether you plan to run mostly at 9V or 12V or whatever. The supply voltage affects the final drain impedance and also the drive level to the mosfets, so the output network may not be optimum across the entire supply range from 6 to 12V. It's a judgment call, and each band is different.

Remember that there are tolerance issues for the toroids and capacitors, so we have several variables that affect the optimum tuning on each module. This will be true for most any solid-state final you build, if you want to max it out.

Mike,

That's the plan. As long as the hot air tool is used carefully on
the top side, the bottom side of the board shouldn't get hot enough
to reflow, and the parts already soldered should stay on.

I'm going to go with a standard hotplate with a piece
of metal over the element. Folks say the temp is
right
when water just boils on the surface,

Going to do one side and then put screw spacers in
the mounting holes and then do the other side. Been
told that is one way to keep the components off of the

hot metal. With a lower powered candle warmer, I
suspect the components would be O.K. touching the
surface.

Also, the hotplate has more than enough surface area
to get the job done.

After reading all the hot plate, candel warmer, toaster oven and other kludge methods for doing SMT, I sprang $99 on Ebay and got a Madell 850B SMD Rework station. It has 2 nozzles, one small enough to do one component at a time. Works great. I use Cash's solder paster in a tube, and just do 5-10 components, hit them with the hot air, and they just snuggle down onto their pads.

Naturally I had to screw something up. I put BOTH 612N's in backwards. No sweat, used the large nozzle, heated them up and tap the board on the tray I work in, and off they come, neat and ready to be put back right side up.

No warming the board, no having to do all the components at one sitting, and only one heat source to mess with. Beats the heck out of the old slobbering iron. Even the tiny 0603 size things went on easy.

Best $99 I ever spent. (Note, they sell "in stores for around $200, but watch the auctions and you can get one for around $99-130 easily).

1747. Wrap-up on ATS 3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-05 07:24:12 UTC
From: kc7fys
Topic: 1747 Message: 1747

Well, I got it into a nice Ginger Altoids tin, and although I'm not completely finished winding all the toroids and making all the band modules, I made my first QSO the other day with JA2 and got a 569 report. (That's quite local for me here in JA1). I went ahead and used a Maldol vertical out on my 4th floor balcony, tuned through my BLT tuner on 40 meters.

All the reviews on eham and elsewhere are right. This is a dynamite little rig. I'm amazed. I can tell right away I'm going to have fun bringing it with me places. And (surprise) will actually have lots of QSOs with it.

I'm rather sad to have cooled the soldering iron, actually.

For my first somewhat serious SMT project--I am thrilled at how simple hot air soldering is compared to all the talk it's getting here on the list. There is a pretty good air soldering tool project at http://hans-w.com/surfacem.htm and if you google it, you'll find others. I was really freaked out about not soldering both sides at once, about having to de-solder U4 to flip it, and just generally doing the Cash Olsen Shuffle. In reality, sections of the board can be soldered at a time, and in the end I started working without the vaunted candle warmer, and had just the same results. It did help to sort of keep the board hotter for the initial big air solder session. I could have done without it, though. Anyway, I'm a believer.

On the air, I just love the stepped sound of bringing in a station. This is my first experience using digital tuning, and it works great even for a dork like myself. Actually it sounds keyboard-like when tuning past a station.

I would like somewhat louder audio, and to be able to turn it down. I have a pretty big rock-related hearing loss at around 3-4K, and am considered hard of hearing by many close to me. That's one mod I might consider doing. I actually find myself confused by the LED and audio annunciation at once. I never expected that--but somehow reading and listening is something I've never done a lot of before. Like chewing gum and operating QRP on a bicycle at the same time.

Also, the software revision--I am suspecting that may be refined sometime down the line when more of the 3Bs are up and running. I look forward to my first experience doing that. It looks fun.

Thanks, Steve, and others for making such a satisfying kit that actually turns into a super-fun radio when all the building fun is finished. I built mine in an altoids tin, just to keep it 'stock,' but used a BNC rather than the provided RCA for antenna connect. The

40-9er, Rock Mite, Tenna Dipper, and BLT were excellent primers for this nice piece of equipment. I anticipate maybe putting it into a heftier housing in the future--maybe something with recessed 'dimples' for the 4 buttons, to cut down on the abuse they may get from handling the rig.

I think I learned a lot in the process of building it.

From the description, I would so no. It generates AFSK. The ATS-3B works only with Pocketdigi.

I find it interesting that for some years, AmQRP promised a stand-alone PSK-31 unitimplemented on the Micro-908 kit. After buying that kit, looking forward to this addition, I see they have now gone to an entirely new kit for PSK. Based on past experience, with their goal of having it ready by "November," I would ask "which November?"

1751. Wrong value zener sent with second run ATS3-B kits

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-09-05 16:52:06 UTC
From: Steven Weber
Topic: 1723 Message: 1751

I just found out I sent 6.8 volt zeners in the second run ATS-3B kits instead of 47 volts ones. Somehow 1N4757 turned into 1N4737 when the order was placed. Maybe I couldn't read my own writing!

The rig will work okay for the moment with out the zener, its just an added layer of protection against high swr. If you put the zener I sent in place, it will likely trip the over current protector when you key the rig.

I'll need to order the correct ones and figure out who I sent the wrong ones to. That will take about a week. Sorry if this causes you and trouble. You know if you have a 2nd run kit from the folder on the CD labled "ATS-3B run2" and is also indicated at the bottom of the title page of the manual.

For those of you who have completed the ATS-3B, in the band filter test and adjustent section, step 3 states:

3. On Band modules using the green trimmers, remove them from the bottom side of the board and relocate them to the top side of the board, then solder into place.

Does this mean that after adjusting the trimmers on the 80/40m modules we need to move them to the other side of the board???

Perhaps you meant "1N4756 turned into 1N4736?" I'm looking through the antistatic bag of my kit and see a "4736" on a diode, so I assume I need a 1N4756 as a replacement.

My folder is titled "ATS3B CD R2" and the bottom of the title page reads "Revised for second 100 kits September 24, 2007," so clearly I have one of the second run kits.

I'll e-mail you my shipping address. Thanks again for all of your tireless efforts!

All trimmers should end up on the same side of the board as the toroids.

I believe Steve was able to ship all kits with bottom-adjust trimmers
that do not need to be temporarily mounted on the opposite side of the
board for access during adjustment:

Dave,

My green trimmers are the bottom-adjust type so it I thought it was odd that it was mentioned to move them. I will scratch out that step in the manual. Thanks.

It wouldn't work for transmitting, as doing digi-modes with the ATS-3B is a whole different scheme. I wish them luck with the gaget, but I'd think a Pocket PC with Pocketdigi would be a better way to go. I'm sure that would work a whole lot better plus be smaller and lighter. A brand new PDA probably won't cost much more than what they will have to charge for the kit. Too bad they didn't go with a color grahics display, though those are kinda expensive.

That was true for the first 100, but after that there were no more
avaliable, so had to use the top adjust ones I had previously bought by
mistake.

There were enough of the brown bottom adjust ones available, (and I bought
every last one both Mouser and Digi-Key had) so those don't need to be
moved. I hope the instructions are clear enough on that point. Its only the
green ones which have the issue.

Mouser might continue to carry the bottom adjust trimmers, its just that
they won't have any more for 10 or more weeks. For Digi-Key, thier now a
non-stocking item with a 1500 piece min order and no indication on how long
it would take to get them. I guess I'm the only one who has been buying
these things and if there is ever to be another run of ATS-3 type kits,
might have to figure out a way to use some other type of trimmer.

From: larrypgrahn
Topic: 1759 Message: 1759

I am at the Check out and Calibrateion part of the kit.

I gave it power and heard the "ATS-2"

Went to "Reference Oscillator Frequency Calibration"
Applied power and heard "CF"

Sent the frequency to 10 MHz

Clicked the MENU and heard the"CO"

DID NOT hear the low pitched tone in the headphones.

Have checked everything as far a soldering orientation of ICs

I need some help.

On the schematic, start at pin 19 of U6 (ad9834) and trace thru the dds output filter to DDS_LO, then on to the 1st rx mixer (U1/SA612) thru the analog switches (U8 and U9) then thru the next mixer U2/sa612, then U3, U4 and finally U5. It will be somewhere in that path. Reinspect all parts on that path. A wooden toothpick can help find a leg that might be not soldered but look OK. Good luck.

Hi Ross.

The ATS-3b protocol is no secret. You can download the whole C source of PocketDigi at pocketdigi.sourceforge.net. Look for the pocketdigi-1.0.10-src.zip archive. It would be my pleasure to help you guys with porting the interface to your new hardware.

I wonder how the solution compares to PocketDigi on Pocket PC. The main weakness of Pocket PC is its high current consumption. From my experience it seems that the backlight takes about half the current. Some of the PDAs are equiped with transreflexive displays, which are somehow readable without backlight.

If I remember it correctly, PocketDigi running on my legacy iPaq 3630 with backlight off takes about 250mA current at 4V. That compares very well to NUE's 8V at 165mA, the PocketPC is even slightly more power efficient. I bet I can buy a used Pocket PC device at e-bay for the price of NUE-psk parts.

I think, that there is an opportunity though for NUE-psk to beat the Pocket PC solution in terms of power consumption by using single small reflective LCD display, powering it from single LiPol cell, optimizing the DSP algorithms and lowering system clock etc. It is a great kit for those that want to build their own computer.

Well, according to the AMQRP Club specs, the NUE-PSK weighs 2.5 lbs - that is enough for me to pass it by - you won't find me backpacking with an extra 2.5 lbs just to do psk. My new Dell AXIM X30 weighs in at 4.9 oz with the standard battery pack. Add to that the weight of the added circuit to hook it up to the ATS-3B and you've got an idea of the weight difference.

1763. A couple of hopefully benign ATS3B R2 discrepancies?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-06 04:28:22 UTC
From: rds_6
Topic: 1763 Message: 1763

I soldered all of the SMT parts onto my ATS3B R2 board this evening. I was going to use my newly modified candle warmer and embossing gun, but I haven't had a chance to borrow a friend's solder paste yet, so I just soldered it all by hand. The TSSOP DDS was the only part I had to resort to flood & wick, which worked fine.

I noticed the following two minor discrepancies (besides the 47-volt zener diode issue):

1) The 0.15uH L4, which was supposed to be marked with a yellow sticker, was instead marked with green marker (or at least I hope it was -- I installed something marked with green marker at L4).

2) The "real U11" MCP120T-3151, which was properly marked with green, had the marking "SL96" on it instead of "SLFJ." I hope that's not a problem.

Also, on pages 15 and 20, the 22K resistors were described as 0805 size, but all of mine were 0603 size, but that doesn't concern me in the least.

I had wondered about that. I figured you would correct me if that
was the case. :-)

Something that might be cheap and easy would be to provide a right-
angle pin header and an extra header socket to build an extender.
I built one like that to be able to access the main-board area under
the band module while the module was installed. It puts the band
module in a vertical position that should allow access to the
trimmers.

From: W2AGN
Topic: 1770 Message: 1770

This was my first attempt at using the solder paste method for SMD construction.
I did not use the hot plate/embossing tool, but purchased an "SMD Rework station."

This thing make working with SMD easier than leaded stuff. I did use the solder
paste in the syringe from Cash Olsen, as it made applying the stuff a snap. I
still have enough left in my $5.00 syringe to build another one (or my QBSA).

The "proof of the pudding" came today, when I applied power...and it worked,
first time! I have built all the ATS series, and this is the first that I had
work right away, no troubles. (I caught, and fixed my reversed 612's early).

Just wanted to share a really NEAT trick my bro-inlaw recently passed on for desoldering misplaced or misaligned SMD components. Using two solder irons like a pair of tweezers works like a champ! But be careful not to flip or drop the dang thing into the black hole (your carpeting)! Actually one of my irons is slightly magnetized and parts seem stick to it? Even when you don't want them to!!!

YMMV Cheers, Steve/n0tu

1776. Hot Air Tools Work

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-08 05:57:32 UTC
From: radio_kx0r
Topic: 1776 Message: 1776

I just built a NorCal SMT dummy load using my modified candle warmer with heat spreader plate, embossing tool hot air device, and the Cash Olson solder paste and method.

Everything worked nicely first try. I can't believe the way the parts dance into alignment when the solder melts!

When I soldered the parts on the second side, I decided to support the board so the soldered parts on the lower side weren't in direct contact with the hot spreader plate - just in case they reflowed. Others have suggested using screws to raise the board - I tried something easier. Just raise the board with coins. I allowed several minutes for the preheat, and then the second side soldered just as well as the first, once the hot air tool did its magic.

Looks like the method and tools are appropriate for the ATS-3B! Now I just have to do the job...

I used the Madell 850B SMD Rework station. I sent the procedure I used to someone else in private email, but it might be of interest to the group, so here it is.

1. Set Air at 2 and Heater at 350 on the station. I used the small nozzle. Too much air and the parts blow off the board ;-)

2. Apply tiny dab of solder with syringe to pads of circuit board. For IC's I used a THIN bead of solder along the pin pads.

3. Place component with tweezers onto pads. I had planned to do a bunch at a time, but found I kept bumping components off the pads, so I ended up doing 5-10 at a time.

4. Place board in metal pan, or on tray. This is just to protect your work surface from heat, although I don't think it is really necessary.

5. Turn on station. It only takes about 30 seconds-1 minute to be ready. Blinking light tells you when.

6. Hold nozzle about 1-2" above component. Watch in amazement as in a few seconds, solder melts and component "snuggles" into place.

7. If you have to move a component, heat as above, and while holding tool in one hand, simply pick up the part with tweezers held in other hand.

No Cup warmers, pre-heating board, etc. It goes really fast. What's neat is you can do a few, take a break, and come back and do some more.You aren't forced to doe the whole baord at one sitting. Oh yes, No problems doing the other side of the board. No components loosening up on opposite side, etc. I did chicken out and solder the LED readout and jacks manually, fearing I might melt them.

I like Cash Olsen's paste because it comes pre-packaged in a syringe. I also got the larger needle he sells for $1.00, as I found the fine one did take a lot of pressure. Solder paste should be stored in the refrigerator, as it does not keep well. The only other sources I saw sold it in bulk, and you wouldn't ever use that much. One $5.00 syringe from Cash will do at least 2 ATS3Bs.

1782. OT: looking for a ride to Pacificon

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-08 17:58:57 UTC
From: John Shadle
Topic: 1782 Message: 1782

Hi,
I'm going to be visiting a friend in San Jose (actually Campbell) and am looking for a ride from there to San Ramon on Friday morning for Pacificon.

I won't need a ride back in the evening since we're headed out of town (camping) for the weekend.

Please reply off-list if you can help me out or know someone who can.

Thanks!
-john W4PAH
Chapel Hill, NC

1784. NAQCC October Sprint

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-09 01:42:25 UTC
From: Larry Makoski
Topic: 1784 Message: 1784

This Tuesday evening, the North American QRP CW Club will be holding its monthly sprint.

Here are the particulars:

Date and time:
Wednesday October 10th, 0030-0230 UTC
(Remember that's Tuesday evening here in the USA) That's 8:30 - 10:30 EDT, 7:30 - 9:30 CDT, 6:30 - 8:30 MDT and 5:30 - 7:30 PDT.

Bands - Frequencies:
80M - 3555-3565 kHz (Be courteous to FISTS operating on 3558 kHz)
40M - 7039-7050 kHz (Avoid W1AW on 7047.5 kHz).
20M - 14059-14065 kHz. General:
A particular station may be worked once on each band. Operate CW only. All licensed amateurs are invited to participate, but only those operating QRP (5 watts or less) are eligible for awards.

Call: CQ NA

Exchange:
RST - SPC (State Province or Country) - NAQCC Nr.
(non-Members substitute power level for NAQCC Nr., e.g. 5W, 1W, etc. Be sure to add the W.)

QSO Points:
QSO with a Member, 2 points.
QSO with a Non-member, 1 point.

Multipliers:
Each USA state
Each VE province
Each country except W/VE
All multipliers count only once in the contest.

Bonus:
If you use only a straight key for the entire sprint, multiply your score by 2.
If you use only a bug for the entire sprint, multiply your score by 1.5.
If you key with anything other than a straight key or bug, there is no bonus multiplier.

Categories:
SWA - simple wire antennas - for those using a simple wire antenna per NAQCC definition.
GAIN - gain antennas - for those using other than a simple wire antenna.

Special Award:
Our special award this month goes to the one who has the most QSO's with our special event call N3A/# in their log. We will have N3A/# calls from all 10 call areas active in the sprint. In case of a tie, the SA goes to the one with the highest score. If a 1st or 2nd place certificate winner also qualifies for winning the SA, the SA goes to the next highest scorer. That is because we want as many members as possible to receive one of our certificates. You must indicate in your report if you are applying for the SA, and how many N3A/# QSO's are in your log.

The following are our operators:

1 call area - N3A/1 - N1LU (NH)
2 call area - N3A/2 - KD2MX (NJ)
3 call area - N3A/3 - WY3H (PA)
4 call area - N3A/4 - AA4W (FL)
5 call area - N3A/5 - AE5BH (TX)
6 call area - N3A/6 - K6BBQ (CA)
7 call area - N3A/7 - WY7N (UT)
8 call area - N3A/8 - WB8LZG (MI)
9 call area - N3A/9 - W9ILF (IN)
0 call area - N3A/0 - NO2D (CO)

Prize:
We have TWO prizes this month.

Karl N3IJR has kindly donated a Hendricks DC40 QRP Transceiver kit to be given away in honor of the NAQCC's 3rd Anniversary this month. Club President Tom WY3H has decided it will be awarded to the highest scoring MEMBER who has never previously won a 1st or 2nd place certificate in our sprints nor won any other physical prize. In case you don't remember if you've ever won anything, here <http://www.arm-tek.net/%7Eyoel//winners.txt> is a list of winners. Club officers not eligible. So if you qualify to be a winner, get geared up for a maximum effort this month to win this very nice prize. Tie breaking procedures will be the same as for our regular CD's giveaway below.

Continuing this month we are giving away a set of CD's to one participant according to the following rules:

1. The participant meeting the requirements below and posting the highest score will be the winner of a set of CD's in the following months: July, August, September, October, November, January, February, March, April, and May.
A. Requirements: The participant must be a NAQCC member and can not have won a CD set previously. Previous winners are:
K4BAI (Jul 07)
K1EV (Aug 07)
KI4GLH (Sep 07)
B. If the highest scorer does not meet the requirements, then the CD set winner will be the next highest scorer who does meet the requirements.

REMEMBER: You HAVE to be a NAQCC member to be eligible to win the CDs;
and there's still plenty of time to join before Tuesday night's sprint.
To join the NAQCC, please visit: http://www.arm-tek.net/~yoel//joinup.html

Entry Deadline:
All entries must be RECEIVED before 2400Z on October 16th 2007. So
submit as soon as possible, especially regular mail entries.

NEW! NEW! NEW!
Be sure to use the new NAQCC Sprint Autologger feature! Please visit
http://home.alltel.net/johnshan/sprintlog.html after the Sprint to send
in your entry!

For further information, please visit:
http://www.arm-tek.net/~yoel//sprintrules.html

1785. Finally building my ATS-3A

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-09 16:19:49 UTC
From: ve3wmb
Topic: 1785 Message: 1785

After much procrastinating I finally started building my ATS-3A last night. I managed to get most of the SMT ICs installed and I can still see today ;-). Fortunately I purchased a magnifying light and a very small tip for my soldering iron. The real challenge was the DDS chip as the leads are nearly microscopic. The toothpick + beeswax trick works great for picking up components.

I have a question .. I haven't been following this list too closely ... were there any last-minute component changes or errata for the 3A? I'll browse the list of postings but before I get too far into the building process I want to make sure that I am aware of any changes made to the 3A before I do something that I will later have to undo.

Thanks

Michael VE3WMB

470 ohm 0603? :-)

Barring that, does anyone know someplace that sells SMT part assortments? I know Dan does, but that's like a 3 week turnaround affair and I was hoping for faster than that.

Many thanks

NightFire Electronic Kits, offer reasonably priced SMT part
collections. <http://vakits.com/>

I'd also check eBay, as I have been buying from Asian sellers for
through-hole 1% metal film resistor collections at a decent price.

There are no cut traces mods to the -3A. The 47ufd cap across the 5V regulator should be changed to a 100 ufd, but some of the later kits were sent with one. The only other thing is the 45 degree rotation of the uP rest superviser chip, but that is documented in the instructions.

From: Michael Harnage
Topic: 1785 Message: 1791

Changing C54 is the most bang for your buck mod.
Although the last run I believe that Steve had a
bigger cap in the kit so check yours first. It should
be at least 100uF.

Search the messages for "keying thump" and "keying
envelope fix" for others that you may or may not want
to do. I suggest build it stock (except for C54) and
if you notice the artifacts associated with the other
fixes then do them.

I finally completed all the band modules for the 3B tonight. I temporarily tacked in the phones jack and attached a 9v battery clip. On power up I heard the sweet sound of 'dah-dah-dit-dit-dit' in the head phones and saw the flash of a 7 on the LED (17m module installed).

I will complete the calibration and band module adjustment this weekend. This was the most involved kit I have tackled since the HW-8 many, many moons ago, and boy was it fun!!

In the meantime I will look for a suitable enclosure. The Altoids tin is fine, but I would like something just a bit larger that would also hold the band modules.

Congrats Jim!

Has anyone else noticed that the plastic case that the
new iPod Nanos' are shipped in, is perfect for the ATS
rigs? Anyone know how to drill holes in that type of
hard plastic without ruining it? They are also deep
enough to hold the extra band modules.

1797. DFE on ATS3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-10 19:47:40 UTC
From: c.gondard
Topic: 1797 Message: 1797

Hello

I have now finished the installation of all components except the 3x2N7000 (these small things are very (very !!) sensitive to ESD, I have some troubles with them on my 2 other ATS3A

I get the 8 on the LED at the first activation and I have performed the calibration procedure for RX described on page 22 of the manual. All seems OK. The DDS is OK ; I can hear a strong signal on RX without the band module, and I can hear the TX signal with another RX nearby. The frequency in TX and RX is changing when I use TUNE UP / TUNE DOWN

I have also tested the menu functions. Most are OK but I have 3 strange things :

1. when DFE is activated (MENU + SPLIT)I can enter a new frequency with the paddle and the LED shows the 4 numbers on the board, but in fact the frequency has not really changed when going back to frequency display; I have noticed that just after the 4th digit an "X" is send

2. I try to determine the firmware version (page 10 of the manual) by holding MENU during power up : no "v", no version given in the sidetone

3. using the keyer : I can not use the 7 dashes to separate several messages in the memory : it seems it is not regognized, but I can enter a long message until the end of the memory. I have try also very low speed with no success

Do I missed something,or is something wrong ?

Thank you for your comments / helps

1798. ATS-3B working but question on the QBSA

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-10 20:12:56 UTC
From: n2uz
Topic: 1798 Message: 1798

Just had my first contact with my ATS-3B from NJ to AZ, not bad. Just had one bad solder connection at U2 pin 3. I am getting 4.2 watts out using the QBSA for power. I have only built the 30 meter module so far, but the others will soon follow.
To build it I used the normal solder method. I pre tinned one pad, used solder wick on that and then grabbed the part with a toothpick that had a small dab of that blue stuff my wife uses to hold pictures on the walls.
I also built the QBSA and may have a problem. The 100 hz digit is not steady, if it displays a 0 it will jump between 0 and 1. If I tweak the trimmer it will jump between 0 and 9. Never can I get it to be steady. All the adjustment were performed per the manual.

As far as the 7 dashes goes, it is NOT 7 individual
dashes but instead hold the dash key down continously
until 7 dashes have occurred. This is a single
character memory marker.

For the DFE, if you enter a freq that is "outside" the normal US ham bands (don't know if Steve changed the firmware for those outside the US) you will hear the "X". Means that you can't enter that freq. You will notice some anomalies with entering frequencies, for example, you can enter 999.9 which will put you at 7.9999 mhz (with the 40m module) but you can't "step up" to 7.999. Reason is that firmware does not check the Mhz digits of the frequency. For 30m the lower limit is 99.9 Khz and the upper limit is 150.0 Khz. So if you enter anything less than 99.9 or greater than 150.0 Khz you should get the "X".

My rig does not give me the firmware version either. Reason is that the test for straight key mode is causing the firmware to skip testing for the menu button. If you hold the dash paddle and the menu button then apply power you will hear the "V1" but then you will be in straight key mode. Simply repower.

1804. 47Z7 MOV in place of 1N4756 47V zener diode?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-11 18:17:49 UTC
From: rds_6
Topic: 1804 Message: 1804

While waiting for the 1N4756 47-volt zener diode to arrive, I remembered I had some 47Z7 47-volt metal-oxide varistors (MOVs). I'm wondering what would happen if I installed one in place of the missing zener. I'm thinking the important parameters are trigger voltage, power dissipation, switching speed, and capacitance. The trigger voltage should be the same, and the power dissipation should be greater (although MOV specs are for transients, so it's hard to compare), so those shouldn't be a problem. I seem to recall MOVs switching slower than zeners, so I don't know if they'd be appropriate for RF. My main concern is that the 4500 pF capacitance rating of the 47Z7 places a 10-ohm @ 3.5 MHz and 1.7-ohm @ 21 MHz capacitive reactance to ground at the output of the PA, which seems like it would not only rob power from the antenna and mess up the PA output impedance but also be low enough to nearly short out the PA output, so it seems like a MOV with 4500 pF capacitance is unsuitable. Is that a reasonable conclusion, or is there a way I could make it work?

Also, when testing my ATS3B R2, I noticed the "Checkout and Calibration" instructions on page 23 of the ATS3B R2 manual refer to the PA transistors as "Q6 to Q8" and the PA keying transistor as "Q4." Shouldn't these be "Q7 to Q9" and "Q6," respectively?

During checkout, I also tried out some of the various functions. A couple of things didn't work as I expected. The LED decimal point lit for RIT, but not for XIT (even though subsequently pressing the SPLIT button emitted the "dit" indicating XIT was being turned off, so it must have actually been turned on, even with the unilluminated decimal point). Also, tuning up in frequency over the 80m band gave the "dit" soft and "dit-dit" hard band limits, but tuning down just kept periodically repeating the "dit" soft band limit, never reaching a "dit-dit" hard band limit. I didn't hook up a frequency counter to see where the DDS actually was in frequency. Are these normal (i.e., firmware "features") or is there something I should do to fix them?
72,
Ross N0GSZ

From: c.gondard
Topic: 1797 Message: 1807

Hello Mike

Tnx for comments

I have now tested all band modules and made alignment with RF signal
All is OK
I can use DFE on all band modules except the 80m module !!
but DDS is moving with TUNE UP/TUNE DOWN on 80m
strange !!

>While waiting for the 1N4756 47-volt zener diode to arrive,

It should show up in a day or two, everyone who needs one should have it soon. Zener for DX kits went out today.

>remembered I had some 47Z7 47-volt metal-oxide varistors (MOVs). I'm
>wondering what would happen if I installed one in place of the missing
>zener.

I doubt you'd get any RF output because of the high capacitance and it would likely cause the overcurrent detector to trip. Better to not use anything there than something which is not suitable.

Chris and all

80m dfe does not work because the test for the
firmware is testing 0x9999 (999.9 Khz) against what
ever you put in. The first test is to see is what you
put in is greater than or equal to 0x9999. It is since
0x9999 is a negative number (1001100110011001)
virtually any "cw freq" you enter will fail and kick
you out.

This is one of the reasons that my version of the
firmware does not have limit checks. The freq is
stored and manipulate as a decimal but the cmp is
using signed integer comparisons. Not gonna be trivial
to get it to work right and I wanted the program space
on the other ATS rigs for other things. I am currently
working on porting my version of the ATS firmware to
the 3B.

I am sure that Steve is tracking these little bugs and
will be releasing updated firmware soon. If you have
not checked out how to reprogram the rig it may be
worth reading up on it...

[shameless plug mode on]
check it out at <http://w1mt.qrpradio.com/ats3.html>
[shameless plug mode off]

From: Jim Fraser
Topic: 1693 Message: 1811

Thanks guys for posting the photo of of the balun and the confirmation of it being correctly wound. I was previewing the QBSA manual and found the drawing to be a little confusing with the start and finish ends of the bottom winding. I will be ordering one these kits shortly to complement by 3B.

Hello Mike

Thanks a lot for this explanation; I understand that it is a small bug in the software. So I will wait a little to see if any upgrade in the szoftware is available. I am a completely beginner in EPROM programation, but I will learn (that is also ham radio !)

Now I get 4.5 watts on 80m with 3 x 2N7000 on 11 volts; As described in the manual it is not possible to use more than 12.5 V, as the overdrive circuit trips !!

I try the 30 module but I need to compress/expand coils in order to get maximum power.

What a pleasure to buid this kit !!

Again congratulations to Steve (and other) for this nice job

John,

Read the thread beginning with:
http://groups.yahoo.com/group/AT_Sprint/message/1508

It would appear by Steve's comments that it should be OK with the 3B.
If sensitivity at the higher frequencies becomes an issue, Steve
mentions a solution...physically switching the positions of L1 and
R18 on the board so that they match what is on the schematic.

From: sm0gns
Topic: 1815 Message: 1815

Hi.

I have been sending some private mail to Steve/KD1JV during the last
10 days without any answers. Perhaps my mail is circulating i
cyberspace?

Now I will try to get it through this way.

I am missing a vital part in my ATS3B kit.
It is U4, 74LVC1G3157 that is missing.

Could you please send me one replacement?

Best regards

Peder, SM0GNS

Took some detailed inspection with scope etc but problem solved.

Error traced, bad soldering on R12 and R13 which meant that input to
first audio amp was wrong and it went into oscillation. This for
info with anybody else seeing the same problem.

Signals are getting through from antenna to headphones.

1821. Call for Winter QRP Foxes

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-15 00:55:12 UTC
From: Larry Makoski
Topic: 1821 Message: 1821

So far we have only a small number of folks who have volunteered to be foxes for the upcoming winter foxhunts which start on Tuesday, Oct. 30th.......Yes that's only about 2 weeks away.

If you participate in the foxhunts PLEASE consider applying to be a fox ASAP via.........

For 40 meters....... http://www.qrpfoxhunt.org/fap40.htm

For 80 meters...... http://www.qrpfoxhunt.org/fap80.htm

And, I know, we call it an application process. Don't let it scare you. Its just our simplified way for you to provide some information and for those of us preparing the schedule to know about your desire to participate.

So..........how about it? Let's get the winter foxhunt season off to a good start.......PLEASE APPLY TODAY.

Apparently, the last two letters are a date or lot code, so are different
than the first batch of these parts I bought (for the ATS-3A rigs). Not
thinking there would be different markings on the new batch, I used the
code from that first batch in the manual. In anyevent, that is the correct
part.

There's an "8" when the power stays down long enough, and is then re-started.

Now...off to wind a zillion toroids! 8-)

Hi John,

I see in another message that you got your 3B to sing on power up,
congrats!. Have fun with those toroids! I only wound enough to
complete one band module per evening, thus it took six days.

I am still looking around for an enclosure, I'd would like something
a bit larger than the Altoids tin to include the band modules. Today
I ordered a QBSA today to help with the band module power adjustments.

Hi Jim,

Yes, at least it passed the smoke test... I'll go through the rest of the checks this evening and tomorrow, and start winding toroids.

I too would be interested in an enclosure large enough for the unused band modules, as well as the rig. Would be interesting to see if anyone else has gone down this road before, to provide some food for thought...

John K5MO

PS : Thanks again for the resistor!

1828. (slightly)OT: ATS3B first outing antenna considerations [help needed]

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-16 06:07:09 UTC
From: kc7fys
Topic: 1828 Message: 1828

Howdy,
I took my 3B down to a somewhat scenic and blustery part of Tokyo bay for an initial outing, what with the XYL being out of town and all. I was able to make some reasonable contacts around JA6, JA2, and right here in JA1 with good reports. Elecraft T1 and BLT went head-to-head and both came out looking good. 'Specially my minty lime-green BLT. I'm afraid of the high SWRs presented to the ATS rig during the T1s tuning routine. (Any comments?)
Anyhoo, I need some antenna application advice. Setting up a wire antenna on a sea-wall. Radial considerations, dimensions, grounding(?) considerations, etc. If you are hip to the flickr.com thing, click on in to some photos of the setup and leave your comments.
<http://farm3.static.flickr.com/2282/1574068849_5703cd90d2_b.jpg>
Don't be afraid of getting too basic with me. Here's the URL, and I'll take the rest of this discussion off-list, which seems appropriate.
Thanks again for the fun rig, Steve.

1832. ATS3B TO ATS3B QSO IN EUROPE

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-16 20:54:39 UTC
From: c.gondard
Topic: 1832 Message: 1832

Hello

My new ATS3B is now installed in a small pills box (made in France), very similar to the famous ALTOIDS box , which is difficult to find in EU !! I will post soon some pictures on my small web page (see qrz.com) and here

Before doing that, I made about 50 qso on the 6 bands with some good DX on 17m and 15m (PZ5RA on 17m, several W/VE on 15m last Sunday) Antenna here is only a 2X20 m doublet with a 450 parallel line, a 1/1 balun (BL1 from Elecraft) and the T1 Elecraft ATU. I have notived that the overcurrent sensing system trips easely when power supply is at 12 volts, so I put 2 x 1N4007 diodes in serie in the power suplly line to reduce voltage to 11 volts. OUtput power is about 4.5 watts on 80m, and drops to 3.5 on 15m which must be in the spec.

Again very pleased to built this excellent kit : congratulations to Steve for this wonderfull job !

I just finished a long QSO on 80m with Paul HB9AXL also using his new ATS3B !! It must be a first QSO of this type in EU !!

1833. No DDS output

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-17 00:22:31 UTC
From: twoube
Topic: 1833 Message: 1833

I'm trying to do the calibration process on p. 22 of the manual, and I can't seem to get anything out of the DDS (at test point 1). The unit does enter the cal routine (I get the CW feedback and the "C" on the display) but if "DDS TP1" is the same as "TP1", I am not getting any signal at that point. I connected a counter, then checked also with my trusty Tek 485. I do measure 4VDC at that location , as noted earlier in the checkout procedure

I can slew the frequency with the up/down buttons and have it "announced" via the Menu button (I think that's it...)

1834. Re: [AT_Sprint] No DDS output

Start with this: Look at the DDS chip under
magnification to ensure good solder joints. Also,
inspect the 60MHz oscillator and make sure it is
soldered good and is working.

From: Steven Weber
Topic: 1833 Message: 1835

Not having a connection to one or more of the clock osc pins is the most common reason for no DDS output. Second is connections at the DDS chip and third is missing/bad connections to the discretes connected to the DDS. Got to be one of those three!

1836. QBSA frequency display with ATS-3b

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-17 15:21:53 UTC
From: n2uz
Topic: 1836 Message: 1836

I have been using my ATS-3B and QBSA for 2 weeks now with the 30 meter module and all is ok. This week I built and checked the 40,20,17 and 15 modules and get good power out on them.
The only thing is that on 17 meters the QBSA is jumping around 5 kc and with the 15 meter module the QBSA just displays the IF freq of 4.9152. The other bands display correctly.

I saw the thread about changing L1 and R18 to match the schematic, but on my QBSA board they are in the correct position. R18 is connected to the collector of Q2 and L1, and the other side of L1 goes to 5 volts.
On my scope it looks like a very small signal coming from the ATS-3B(I take it off DDS LO output via the 3 pf cap supplied.
Any ideas , should I try pin 20 of U7?

1838. RIT on 80m with ATS3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-17 21:03:30 UTC
From: c.gondard
Topic: 1838 Message: 1838

Hello

During one of my QSo on 80 this evening, I have noticed a strange behaviour of the RIT function on 80 m :
RIT is ON when pressing SPLIT : a small dot lights on the LED : OK
when using TUNE UP or TUNE DWN, the frequency can move only above or under the central frequency; when you try to cross it again in the opposite way, an "X" appears on morse, and the frequency move is blocked

I try on all other bands, and the RIT is OK : a "0" appears when back to the central frequency, and I can move over or under it several time in both directions

I believe that it is related to the DFE problem on 80m (see message of Mike W1MT

I have posted also a picture of my new ATS3B on the Files Directory

Chris,

I was thinking about the DFE problem on the way home
from work today and realized that my explanation was
wrong but the result was the same.

Real reason: The lower limit for 80m is 999.9Khz when
a freq is entered it will always be lower than
999.9Khz and thus will fail the lower limit test every
time. The firmware only checks the KHz and tenths of
KHz digits of the frequency.

Hey gang;

All of these 'operational' software bugs brings up a question.

I imagine a new software release may be desirable in my future. My new laptop ONLY has USB, video, audio, ps-2, card slots and 1394 I/O (and no parallel or serial ports)....So is there a decent external converter for use with the ATS-3B's programming pins/(port) ?

Sorry if this has been asked before and MANY tnxs for a reply.

Probably the "best" solution would be the
MSP-FET430U28 USB FET tool. I have not tried it but it
looks like it should work. Down side is that it costs
$149. Olimex has the MSP430-JTAG-Tiny that should work
and it costs $70 plus shipping. Olimex also has the
MSP430-JTAG-ISO but it costs $130 plus shipping. All
these devices are USB.

K...thanks for the excellent info Mike. It's a good start.

Does anyone know of a generic device as I run Linux ONLY and am looking
for a device that does a GOOD job of translating USB to RS-232 and/or
Centronics parallel interfaces ? I guess this device should also be usable
for other tasks, like GPS interface etc.

I am assuming there is a good rs-232 or parallel programming interface for
the devices used in the ATS-2/3x series. Maybe NOT ?

TIA for the answers.

In theory, that can't possibly happen. A different kind of test is done in the tuning routine than what is used in DFE. My rig works as it should. I can't think of any reason your rig should behave that way. The only Morse characters which can be sent when in RIT or XIT is a dit or ditdit. Can anyone else duplicate the problem?

The only glich I noticed is the DP doesn't come on when you enter XIT mode as it should, but does come on if you tune up and then down past the center frequency, once the "0" flashes.

Digital Interface Questions for Steve:

As my plan is to package the digital interface in the same enclosure as the ATS-3B, I have a couple questions:

1. Since the voltage requirement for the digital interface using the OP Amp is 3.5v, would the output of the 3.5v regulator in the ATS-3B be sufficient to also power the interface?

2. Can the audio inputs for the interface be directly wired to the audio phone jack of the 3B?

Hello Jonathan

Thank you for your comment; the top of the box is covered with a plastic film; the image is taken from the file given by Steve in the kit package; I have only added some personal data; the plastic shhet is directlu printed on a laser printer, ang glued on the top of the box.

I have no holes drilled in the box in order to take in place the board; I have simply glued the 4 spacers on the inner surface of the box

I have also added some pictures on files directory of this site

I suspect that Atten and Madell are actually from the same manufacturer and just have different names silk-screened on the front. The Atten 850D I have looks identical to pictures of the Madell 850D on eBay. Hakko is the big-name brand and is likely to cost more but get you higher quality.

Yes Hakko is a "brand name", but I would be careful about the assumption that you necessarily get a higher quality. If it does cost more, then perhaps yes, but a lot of brand name tools, for example DeWalt Power Tools for woodworking and construction, also have a "price-point" or as I call them the "throw-away" line that is intended for the home consumer (weekend DIY'er) that buys from big box stores.

I believe Weller has some Weller branded products that are the "throw-away" quality, but other than the tiny premium for the name, is the same quality and durability as the store or no-name brand made in China models.

BTW, I just did a _quick_ search on eBay and I did not see any Hakko brand hot air rework stations for less than ~$450. I'm curious about what the model number is.

There are a number of "brands" of SMT work stations that are, in
reality, all made by the same people in the same factory in Asia.

I have had good luck dealing with these folks outside of Boston
http://store.sra-solder.com/

They are helpful, can be reached by email or phone (yup they even
answer the phone ... imagine)

For the average Joe Ham some of the inexpensive work stations will do
just fine. I use one that was really expensive and top notch and one
that cost less than 150 bucks. I tend to use the cheap one more often.

Date: 2007-10-18 21:08:27 UTC
From: Steven Weber
Topic: 1838 Message: 1859

Chris, your right. RIT does not act right on 80 meters. In fact, you can't even turn on XIT. Maybe thats where the X was coming from, XIT turning on.

Apparetnly, this is only a problem with the early release of the kit, but might affect the first 100. Not sure when I made that problem go away, so its possible that not all of those 100 have the problem. They all have the 80M DFE problem, as I only recently fixed that.

The RIT problem only affects the 80M band, but XIT won't turn on on any band. XIT is something most people don't use too often or at all. If you don't use 80M much, than RIT and DFE not working right on that band isn't too big a deal.

In any event, I'll up load the firmware later tonight which fixes those problems and a few other little bugs, like not being able to access the firmware version number unless your in straight key mode and the overload warm boot reset not restoring all the current perameters.

If anyone wants thier MPU reprogrammed, I'll be happy to do it and pay for return postage. The most resent kits sent out should be fine as they are.

Not positive, but from what I researched prior to my own purchase, the
Atten and the Madell are exactly the same.

1864. V3 firmware

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-19 02:44:03 UTC
From: kd1jv
Topic: 1864 Message: 1864

For those of you who can program the mps430, the latest version of the firmware is now in the files section, as a zipped file.

I tried to see if a simple PC interface could be built for programming the MPU in circuit, but it didn't work. Looks like will have to copy TI's programmer, which uses a 74HC244 non-inverting tri-state buffer. I'll copy that circuit and post in the files section also, in case anyone wants to build one. It does require a PC with a parallel port.

For those who haven't soldered in the MPU and would like it reprogrammed, you can send me just the chip. If you just put it in a letter envelope, it mess up the leads. It can be sent in an envelope, but use a piece of cardboard with a hole cut in it to set the chip in, also put it in the static bag. Or use a padded mailer.

If I were you, I would certainly try the simple one resistor one capacitor interface first. If it works, there is no need for the op-amp solution.

From: n2uz
Topic: 1836 Message: 1866

----------SNIP----------
> The only thing is that on 17 meters the QBSA is jumping around 5 kc
> and with the 15 meter module the QBSA just displays the IF freq of
> 4.9152. The other bands display correctly.
> On my scope it looks like a very small signal coming from the ATS-3B(
> I take it off DDS LO output via the 3 pf cap supplied.
> Any ideas , should I try pin 20 of U7?

Success at last
I swapped L1 and R18 and no change(don't bother doing), 17 and 15
meters still bad(jumping). then I measured with my scope the p-p
voltage at the collector of Q2 as follows:::::::
80 700mv
40 1.4v
30 1v
20 680mv
17 600mv
15 590mv
Looks like you need at least 680mv here.

That's when I picked the signal off of pin 20 of U7 instead of the DDS
LO in the ATS-3B, P-p voltage at the collector of Q2 for 15 meters is
now 1.1v with all the others bands about doubling in value.
All is ok now, rock solid display on all bands(except of course the
occasionall flicker of the least signicficant digit.

1867. Altoids tin holds five band filter modules

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-19 15:55:09 UTC
From: rds_6
Topic: 1867 Message: 1867

By orienting three band filter modules lengthwise horizontally across the middle of an Altoids tin and one band filter module vertically at each end of the tin, I was able to get all five unused filter modules not only to fit in the tin but also to be individually accessible without disturbing any of the other band filter modules. I epoxied some surplus six-position female connectors to the inside of the tin to hold the modules by their six-pin connectors.

I posted a photo in the group's Photos section at:
http://ph.groups.yahoo.com/group/AT_Sprint/photos/view/5615?b=1

I went with a "retro" 20th-Century visual theme using industrial gray spray paint and rubber-stamped lettering in oil-based ink (oversprayed with clear coat). It's not anywhere near as cute as an MS Paint color drawing on a label, nor is it meant to be. Given the practically zero cost of Altoids tins, I may make up a few other tins that can be interchanged similar to "skins" for MP3 player software, etc. I'm thinking a WWII-era military boatanchor visual theme would be amusing and similarly anachronistic. If I can find some small sans-serif stencils, I might try black stenciled lettering on gray paint for more of an aerospace component look.

1869. Simple programmer interface

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-19 21:08:42 UTC
From: Steven Weber
Topic: 1838 Message: 1869

Turns out the schematic for the TI programmer had the pin out to the DB-25 connector all wrong. I buzzed out the connections on my programmer and low and behold, the simple resistor only interface works!

All you need is a male DB-25 connector for the parallel port, a 7 pin SIP pin to plug into the ATS board, 5, 22K resistors and 1, 220 ohm resistor.

We'll number the pins on the ATS board left to right as 1 to 7, ground being pin 1.

ATS pin >> resistor >> DB25 pin
1 none 18 to 25 (all grounds connected together)
2 22K 16
3 22K 1
4 22K 4
5 22K 3
6 22K 2
7 220 ohm 12

The resistors do a voltage translation from the 4-5 volt output of the parallel port to the 3.5 volt supply of the MPU. The resistor values aren't very critical, a size up or down from those shown should work okay.

For instructions on doing the programming, see W1MT's web page <http://w1mt.qrpradio.com> You'll need a XP machine with a parallel port to run the IAR software and use the programmer interface.

Hi folks,

Have a problem to connect and downlaod to the controller:

* soldered this cable
* IAR settings: followed instructions of W1MT, except device:
MSP430F1232
* compilation successful
* ATS3B running, then Ctrl-D, start debug:
* a window comes up: Emulator, "initializing hardware"
* in headphones some puls noise (LPT1 seems working)
* after a few seconds a new window: Emulator, "fatal error:
security fuse blown. Session aborted"

Isn't the controller memory rewritable?

Double checked cable and IAR settings.
PC: XP
IAR: V4.09A

Tried the same with:
PC: W98
IAR: V3.21A
About the same behavour.

Any idea?
Perhaps the full project (not just the .s43 file) could help?

Tnx es 73, paul

I did the intial tests of the interface with IAR version 2.31C

Just tried it with the newer version 3.4B and had the same "fatal error" message come up. Then I tried my TI programmer and it worked. Then I tried the simple programmer again and it worked! I have no idea why it didn't work at first (tried it several times), then started working, and kept working. Also tried closing IAR and restarting it and it is still working now.

I'll have to try programming another board with a different version of the firmware and try to figure out whats happening.

Folks :

I am happy to report that my ATS-3A works !

I just made an ARCI contest QSO with K4AXF on 40M. I am getting about 2W out with 9v in!
I still have to build the other band modules and package the rig up but no problems encountered with the rig so far.

I used "tack one corner first" soldering technique and followed Steve's suggestion of using a toothpick and beeswax for moving some of the smaller components around.
I also followed the "best practice" of building inside a small cardboard box lid to avoid losing
components and that worked great.

This is an amazing little rig. I was skeptical that I could actually build this rig and make it
work but I bought the smallest tip I could find for my soldering iron and took my time and built very carefully and that approach paid off.

My kit had a 22uf cap for C54 and this is what I installed. I am hearing a noticeable thump on T->R transition so I will try changing this to 100 uf and see how that works.

Thanks for the feedback.

Okay Guys,

I hate to admit such a stunning level of ignorance, but not only have I never built an SMT radio, I have never used a 0.7mm plug for power. So... I need some BASIC help: is the short, square terminal the + or - terminal, and how does one attach a wire to it?

Tnx,

Tim KX3H

I think the answer to that is: No. I had a similar need with a JTAG programmer for another device and ordered a USB Printer Port. Unlike USB serial ports which come with Virtual Comm Port drivers, the USB printer port does not include a Virtual LPT Port. I only presents as a printer interface in applications that actually want to print. I searched for a few days for a suitable driver, but it appears that nobody provides one.

Since my need was for a desktop machine, I ended up ordering a PCI card. For a laptop machine, you probably would need the USB-based programming cable.

1894. low power out on 40 meters

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-22 17:24:56 UTC
From: n2uz
Topic: 1894 Message: 1894

I don't know if this is normal, but I am getting lower output on 40 meters. With the voltage around 11.3 volts I get between 3.75 and 4.2 watts out on all bands except 40. There I can only get 3.1 watts out. I am using a calibrated Tekronix 100 MHz scope to make my measurements into a known good dummy load.

The waveform looks like it has 3rd order harmonics, but only on the positive peak of the sine wave (more like a double dip). The other bands are ok, granted not a perfect sine wave, but very close.

The square wave at TP1 is the same for all bands. I removed all of the LPF parts from the 40 meter module and all checked ok. Problem has to be in the module, but everything checks out ok making me think this might be normal for 40 meters.

On any of the lower banks, I don't get any increase in power by moving the turns on L1 or L2.

Has anyone have a similar reading?

Jerry, N2UZ

1895. Anomaly with Iambic B mode timing?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-23 15:03:39 UTC
From: ve3wmb
Topic: 1349 Message: 1895

I have had very little air-time with my ATS-3A but I have noticed an anomaly with the Iambic B implementation and was wondering if anyone else has as well, so I searched the list and found the post below.

Let me start by saying that I have been an Iambic guy for 26 years so my brain and fingers are hardwired for this mode of squeeze keying.

What I am seeing is that most of the time when I try to "R" is that I am getting an "F". After much playing around (with other iambic B keyers as well) I have convinced myself that something isn't quite right with the B-mode implementation in the ATS-3A firmware.
I am still trying to characterize it, but it seems like the window of opportunity to "insert a dah" is very short. I think in most implementations of iambic B that when holding the dit paddle and then tapping the dah paddle, the dah is accepted anytime before the second dit is generated. What I have observed on the ATS3 is that it seems like the dah must be tapped during the actual generation of the first dit. It seems like this window is shorter than normal. If I am really extra quick I get an "R" otherwise I seem to get an "F".

I will do some more digging, both into the specification for the timing for iambic mode B as well as the ATS-3 firmware sourcecode and let you know what I find out.

From: Rob May
Topic: 1896 Message: 1896

That's what I get for not paying attention. A fairly easy fix that I thought I might share for someone in the same boat. Since it's only six pins it's easy to bridge the three pins on each side with solder. A soldering iron in each hand will melt the whole lump of solder on each side and the part can be lifted off the board. A little work with some solder braid and you can try again! Worked great for me. It was the last part that I put on. It was great to hear ---.. in the phones. Now to build the rest of the band modules and align the rig. Woohoo!

There is a section of code in Steve's version that
looks like this:

bic #FLB_EXTRAEL,&bflag
mov.b &P2IN,r11
bic #0fffch,r11 ; dit and dah down

cmp #0000h,r11
jne sp_lp2
bis #FLB_EXTRAEL,&bflag

sp_lp2: cmp #0009h,r6
jne sp_lp2

Change it to:

sp_lp2x: bic #FLB_EXTRAEL,&bflag
mov.b &P2IN,r11
bic #0fffch,r11 ; dit and dah down

cmp #0000h,r11
jne sp_lp2
bis #FLB_EXTRAEL,&bflag

sp_lp2: cmp #0009h,r6
jne sp_lp2x

This will let B work till the space is over. Let us
know if that helps or hurts ya?

A strict implementation of B mode would cause an extra and opposite element to be added anytime both paddles are closed. But this can cause the extra element to be added really easy if your not careful. My Patcomm 9000 does this and drives me crazy. Therefore, I made the "both paddles closed" test happen at the end of the dot or dash. This allows dot and dash memory to work like it does in A mode, but doesn't tack on the extra element unless you really want it, by holding both paddles closed until the end of the element being sent. This is usually not a problem at high code speeds, but might be at slower speeds.

I took my 3B out to the park last night and had a pretty bad
session--no fault of the rig, just a bad location--lots of
environmental QRN from city stuff.
I noticed this--and will describe it in my own less-technical way.
When tuning in stations, I hear them as I scan past, stop, tune them
in so that my CW tone is on pitch with theirs--naturally. (Right?)
Anyway, without fail the signal is several times louder and easier to
copy if I tune past it so that it's at least a full octave lower,
presumably below A440, right? Does this mean that my receive window is
peaked at a frequency below what it's supposed to be? I would assume
the filter would center on zero beat with the received station. If I
do that, it sounds like it's over in the skirt, and is quite quiet.
Is my expectation right here? Did I install a capacitor wrong somewhere?
Thanks,
Jonathan 7J1AWL/KC7FYS

Steve :

That probably explains what I am seeing. I'll try the code mod that Mike suggested once I have the necessary tools to reprogram the MPU. I've been practicing my R's a bit and if I am quick I am getting a pretty good success rate so maybe I can live with it as is, at least
for a while.

The good news is that I now have 40m/30m band modules working with about 4W out at 11v in and the rig is now packaged so I am ready to roll for this weekends Polar Bear outing.

Its a great feeling to have a rig work first time and it is definitely a reflection on the quality
of the manual.

Michael VE3WMB

P.S. I am still getting some audio thumping on the TX->RX transition after replacing C54 with a 100uf cap (I even tried an extra 100 uf in parallel) so I will have to look at some of
the other T/R mods.

Thinking about it this morning I realized that the
firmware does polling on the paddle ports and is not
interrupt driven. So that means if you are used to
just tapping a paddle and expecting it to insert a dah
or dit you might miss the poll event. You will need to
hold the paddles closed a little to ensure that the
test is executed. Experiment.

On the "thumping" look at my photos on the group
website to see where I put the serial R and shunt C
for the control lines.

1903. Over driving on 30 meters

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-24 11:59:02 UTC
From: Buddy Brown
Topic: 1903 Message: 1903

I finished my ATS3B and am in the process of tuning the Band Modules.
Everything is working fine business and I am "tickled to death" with it.
However, I am noticing an anomaly with 30 meters that I haven't been
able to figure out. I am using my QBSA for these tests and adjustments,
and am transmitting into a dummy load with the QBSA wattmeter showing
"0" power reflected. So I know the load is not reactive. But, with the
30 meter module in the rig, the protective circuit in the radio is shutting
the rig down and displaying an "E" just as if there is a large SWR being
seen. This doesn't happen on the other bands. I can't get a power reading,
because the rig shuts down too quickly, but I did notice that when I reduce
the voltage to 9.2 volts the rig keeps transmitting and the wattmeter sees
4.25 or so watts, still with no reflected power.
I also just noticed that the frequency readout on the QBSA changes from
10.110 MHz to 15.247 MHz. I have not been able to hear this on my
TS2000. I can hear the 10.110 MHz signal but not the 15.240 MHz signal.
I thought that the rig was transmitting on both and causing the problem,
but apparently not. It looks as though the rig is just transmitting too
strong
a signal on this band.
Has anyone else noticed anything like this?

Buddy - N5BUD

1905. physically securing Toroids to the Band Module Boards

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-24 13:23:24 UTC
From: ve3wmb
Topic: 1905 Message: 1905

I am a little concerned about wear-and-tear on the toroids on the band modules .. especially the ones with the very small gauge wire. Any suggestions on what I might use to secure the toroids to the board? A bit of Epoxy perhaps?

In my ALT tuner I used the trick that Doug Hendricks suggested which was to use a small sliver from a hot-glue stick and then slightly heat the coil with a hair-dryer / heat-shrink gun to melt the glue. This worked well.

I am wondering if this has any significant effect on the inductance of the coil? It doesn't matter a lot in a tuner but it would on the ATS-3. Maybe I'll dig up a spare core and try this to see if there is any difference before and after. Any other suggestions ?

If it's "permanent" I use two part expoxy or silicone. If it's something I think I might want to mess with again I use hot melt glue. Sometimes with a sensitive tank circuit like a VFO the glue might detune it ever so slightly but for something like a matching network it shouldn't affect it.

Double-check the turns counts on LF1 and LF2 and caps values for
CF1-CF4. You could also try changing the spacing of the turns on
LF1 and LF2 (often in opposite directions) to increase (needed in
your case) or decrease the input impedance presented by the filter.
4.25W on a 9.2V supply does seem rather high.

Michael,

You're right to be concerned about the fragile band modules. They are the most vulnerable part of the radio, especially in the field. I used small dabs of 5-minute epoxy to secure my toroids to the board. You just need a dot under each, opposite the side where the windings are attached - no need to cover the whole winding. Don't do this until you're really finished with tweaking the coils for best power output.

Be sure to clean the board with alcohol or other pcb cleaner prior to using the epoxy - otherwise the glue may not adhere well.

I get almost 5W with 12V to my ATS-3A on all 4 bands, after making some tweaks, so the toroids are OK. I checked harmonics with a spectrum analyzer, and they're suppressed well. The toroids warm slightly, especially on 20M, if you hold the key down.

Gluing the toroids down is preferable to ripping one loose while changing modules in the field.

The hot glue method sounds OK. I don't know how its RF properties compare with epoxy. I like epoxy because you can control the size and position of the dab. I just got a Heathkit QM1 Q meter at a local hamfest, so I could test these adhesives and report back. The Q meter can detect changes in the inductance and Q caused by the dielectric properties of adhesives. Stay tuned - I want to answer this one for myself as well as the group.

Take a look on the Photos section of this site, and in my part you'll find images of my band modules.

Go easy with the adhesive - just a dab...

First, the side tone in the rig is generated by software, so it does not represent the actual offset transmitted by the rig. The side tone frequency in the B is 608 Hz, which matches the 600 Hz peak in the audio filter pretty closely. Therefore, the received signal should peak very close to the tone of the side tone.

Its possible you don't have the BFO trimmer set properly or there is a bad solder connection in the audio filter. One test is to connect the audio up to PC audio spectrum analyzer and see at what frequency the audio peaks at. Should be 600 Hz. Another it to use another rig to see if the frequencies match when talking between the two.

Ted,
I used a yellow version of Blu-Tack, namely HandiTak, which was $0.97 at Walmart, of which about 2% of the quantity in the package was enough to secure all of my toroids. However, while visiting another QRPer who has a fancy HP Q meter, I wrapped some of the HandiTak around a random air-core coil and observed an extremely slight change in Q. While I didn't think much of it, he said that other materials he has used to secure toroids (he prefers E-6000 silicone sealant) do not change the Q whatsoever, and he advised me against using anything that changes the Q in the slightest. Since I don't have any spare enamelled wire to rewind the toroids after inevitably breaking a few wires if I were to try to remove the HandiTak, I'm going to leave it in place and see how my ATS 3B R2 performs before thinking about removing it.

Hi

Has anybody tried a small square of double sided foam tape between the
circuit board and the toroid? I think the foam is some form of polythene.

1915. Finally started my build

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-25 03:51:28 UTC
From: Garry
Topic: 1915 Message: 1915

As the header says, I finally got all other projects out of the way as well as other commitments. Whew. I have to say that the first little while was totally discouraging though. I spent 3 hours trying to place and solder capacitors and at the end had 5 satisfactorily installed. Time to re-assess the situation.

First I found a nice heavy machine vice to secure the circuit board to keep it in place and that eliminated one issue, then I went down to Canadian Tire and picked up a heat gun to try that.

I tried the heat gun on an old circuit board. Let me tell you, if you are a ham that is inclined to scavenge parts from old circuits, this is the tool. It works amazingly well and no tedious solder sucking etc.

After that experience I decided to have a go with the solder paste and the remaining .1 caps. Done in a few minutes. What a difference once I learned how to get the paste out and sticking where I wanted it on the pads. I'm thinking that the first little bit of paste may have been slightly dried out as it gave me trouble but now all seems to be working well although from time to time I had to use a toothpick to smear the glob of paste where I wanted it.

I stopped with the .01 caps all installed. That was enough for today as I had used up plenty of time to get where I now am. By the way, the solder paste/heat gun method leaves a much neater finished product as the capillary action (I think it is) causes the component to center itself on the pads which leaves parts placed neater than I could do with the solder iron method

I've got plenty left to do but I have to admit that I was about to post a plea for someone to build this thing for me, at least the main board as I figured I could handle the band modules. I really have wanted to get one of these since almost a year ago when I first heard of the ATS sprint etc but the fact that they had sold out and were no longer available coupled with the fear that I could not do it kept me from trying.

I still have no idea if it will work or not when done but at least I will have the challenge of building it and I am taking real care and cross checking each component placement as I go so hopefully no errors there. My wife (also a ham) looked at the tiny caps and just laughed and walked away. Not for her I guess hi hi. I think her comment was that she was glad it was me and not her that had to build it.

When I get it done, and working I hope to take it down to the beach and try a half wave end fed at the waters edge. Always hear how good

antennas work when down at the salt chuck and I want to find out for myself. With this rig and it's minimal size, setup should be a breeze.

well that's enough bandwidth for now.

Garry,

Good luck on finishing your build. You are ahead of me - I'm waiting for a snowy day and sufficient motivation before I start with the solder paste.

When you get the rig finished, you'll be amazed at what it can do in a good location. Here's a testimonial:

I took my ATS-3A up to the mountain park near here a couple of weeks ago - I used a fishing pole to hang an extended double zepp, cut for 20 meters, between two ponderosa pines. I sat in a meadow about 1000 feet above the plains and cities to the east, called CQ on 14.060, and had two nice, solid, ragchew QSO's with stations across the country. The third QSO was the amazing one - I contacted W9XS/M - he gave me 589/QSB and I have him 599 - he was solid and near Chicago. Then he told me he was on a BICYCLE travelling 17 mph, running 100W with an IC706 and a CB whip on the bike! There he was, 599, coming out of my Altoids box up in a field full of dried horsemint plants...and sending pretty good CW considering what he was also doing. Somehow he was copying those three little 2N7000's out there on the road, riding in a 20 mph wind. We QSO'd for 15 or 20 minutes, solid, both telling each other how amazing this was. It didn't hurt that the lobe of my zepp was right on him, and it was late afternoon on the path.

Later, after I dropped the antenna and rolled it up, 11 wild turkeys walked out of the woods right behind where I'd been sitting....

The ATS rigs can deliver many surprises!

I ragchewed with K5TF in Atlanta twice this fall with the ATS-3A, both times from campsites in the woods. The first time I was camped WEST of Laramie Peak in Wyoming (wrong side of the mountain); the second time I was camped in the local mountains near Ward, CO, a few weeks later with snow falling on the tent. Both times I used a dipole strung through pretty thick woods. Dick was running 2 watts both times, with a loop.

Enough said - Steve created an amazing radio.

Thanks.
That's very helpful. I'll crank that up this weekend. It's quite possible I didn't do my initial calibration correctly. When I engage in a QSO, I hear the received station best around what I would identify as maybe 250hz--if the note I'm imagining has a fundamental an octave below A440 on the piano. (Can you tell that's my background?)
I'll let you know.

Carey :

I can't measure the impacts on Q, only on inductance .. both are important in this case. This would be a great experiment to try.

I found the hot glue trick very easy to apply on my ALT tuner but I am reluctant to try it on the ATS3 without some idea of how this impacts the characterstics of the coils.

Cheers,

Michael

Michael,

I just ran Q measurements of 4 toroids using different glues. Here's the short version followed by the technical details:

I wound five T68-6 cores with 26 turns of #22 wire. All measured about 3.75 uH on my AADE L/C Meter II. I measured the inductance and Q of each inductor before applying glues to four of them. The fifth was left as a control.

Here are the results:

Coil #1 Q w/o glue 207 control Q later w/o glue 207
Coil #2 Q w/o glue 207 5 minute epoxy Q with epoxy 206
Coil #3 Q w/o glue 208 hot glue Q with hot glue 206
Coil #4 Q w/o glue 204 Duco cement Q with Duco 204
Coil #5 Q w/o glue 211 GE silicone 1 Q with silicone 208

Inductances with glue all measured within 1% of initial values on the AADE L/C meter. Any inductance changes were beyond the accuracy of the meter and methods, and not significant.

The changes in Q are so small that I think you can use any of these glues to mount your toroids. I used a large amount of glue on both sides of the full windings for these tests. Much less glue will be required to secure a toroid to a board. In practice any reduction in Q will be negligible.

The Q's were measured with a Heathkit QM-1 Q meter I recently obtained at a hamfest. I have been through the manual and checked out this instrument, but so far I have no way of verifying the absolute accuracy of these measurements; nevertheless, the consistency is amazing. I was

very careful when adjusting the settings of this vintage vacuum tube instrument. It is interesting that none of the Q's increased, since we expect only degradation. All readings were done several times to check for consistency. Getting to 1% precision with a QM-1 is stretching the limits of the machine and operator.

All glues were allowed to cure about 10 hours. The silicone might need longer to complete its cure, based on my experience with the stuff.

It is possible that there might be effects at high levels of RF that don't show up in these low-signal measurements.

What I've learned from my experience is that the inductance of these toroids can change by 5% or more just by bumping the turns together or apart. If they're wound loose, ordinary handling in the field will cause them to change how they perform in your rig MUCH MORE than any effect caused by the glues I tested. Therefore I recommend you glue down at least one side of each toroid after you're sure you've got them adjusted right. It can even be suggested that extra glue on the top sides might make these coils more durable - but I haven't done this on mine.

Comments on adjusting your filters: You should do your adjustments with the supply voltage you plan to run with mostly. It's also very important to monitor the current to the rig. Since you're changing the impedance seen by the PA, you can vary both power output and efficiency, sometimes one at the expense of the other. It's a judgment call, but you need to watch both numbers. You don't win if you get 7 watts out of the rig and then burn out the mosfets! 5 watts with 12 volts is possible for the ATS-3A.

The reason no one can tell you how to hit optimum is that the inductance varies several percent just by how you wind the turns. The cores have some small variation lot-to-lot. The capacitors have tolerances also. It all factors together to determine the match. In the end you may have to play with adding and subtracting capacitance as well as squeezing or spreading turns. You can take a small cap, a few pf, and experiment to see if adding capacitance helps or hurts. Go easy, be patient, and don't leave the rig keyed too long - it's trial-and-error and a multivariable network, but you really can optimize these filters. Think "nice compromise".

In the end you really should check the rig's spectral purity, if you have access to a spectrum analyzer. As long as your changes are small, you should be OK. Large changes are NOT required, and the rig should be clean as long as you're not messing around with the basic design numbers for these filters.

Thanks Mark -

I just noticed I forgot to mention the frequency of the Q
measurements -all Q measurements were at 7.9 Mhz.

This morning I realized I could test the toroids' Q's at 13.8 Mhz,
the max I can use and still achieve resonance. All five toroids
measure Q's of about 195-200 at 13.8 Mhz, including the control
toroid, which has no glue. So we have no significant degradation due
to the glues at the higher frequency. We should be OK on 20M.

1924. which PDA for PocketDigi?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-26 17:39:35 UTC
From: John Shadle
Topic: 1924 Message: 1924

Hi all. Just wondered if anyone had recommendations for a decent PDA to run PocketDigi. Hoping to pick something up on eBay for use with the ATS-3B.

All I have now is a Palm Zire m150, which I'm pretty sure won't work with PocketDigi (which requires Windows CE).

Thanks.

1926. Q vs Wire Gauge

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-27 17:04:03 UTC
From: radio_kx0r
Topic: 1926 Message: 1926

Since we're supposed to use #30 wire for many of the PA filter toroids (LF-1 and LF-2) in the ATS-3B, according to the manual, I remembered that we used #26 in the ATS-3A; I wondered if the smaller wire affects the Q enough to measure.

I did a quick test to see how much the Q changes when we use #30 vs #26 magnet wire. With a T30-2 core, I wound 16 turns of #26 and made an inductor measuring about 1.7 uH. I wound another one with #30 and measured it to compare:

T30-2 16T #26 1.3uH Q=94 @ 7.9 MHz
T30-2 16T #30 1.3uH Q=88 @ 7.9 Mhz

T30-2 16T #26 1.3 uH Q=110 @ 18 Mhz
T30-2 16T #30 1.3 uH Q=103 @ 18 Mhz

Then I removed the #30 winding, replaced it with #26, matched the inductance by crowding the turns, and measured about the same as above - verifying that the variations are due to the wire.

I did similar tests on large T68-6 cores and I found a 15% reduction in Q with 26 turns of #30 vs #22.

This is no big deal. The performance of the ATS-3B rig may not change enough to be measured if we change the gauge from #30 to the larger #26. Nevertheless, I think #30 is harder to work with than #26, so I'm planning to wind #26 on all the toroids where it will fit...unless someone like Steve says I'm nuts. #26 is easier to wind, strip, and adjust.

The #30 should be just fine...no one should rewind their toroids...I'm just obsessed because I can measure the difference with my Q meter. The toroid with #32 still has to be done with #32 in order to fit the turns.

This is what happens when you go to a hamfest and walk out with a Q meter.

1928. SMT questions

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-30 01:35:07 UTC
From: John
Topic: 1928 Message: 1928

I bought a 3B kit a few weeks ago, but have been hesitant to start building it. I tried soldering one of the "741" resistors and found it very difficult to pin down with my 1/32" tip. I've built a dozen or so Heathkits, a dozen or so years ago (age here is 60+), and always thought I could build them better than the average ham. (My HW-8, built in the 70's still works fine). But I don't think I can build this 3B with a soldering iron.

So I'll give this "reflow" methodology a try. I read the info at the Cash Olsen web site and some of the comments here, but I still have a few questions: (sorry if I missed any obvious answers already posted)

1. Why do we need the hot-plate? Doesn't the hot-air gun put out enough heat by itself to quickly heat up a local area and flow the solder?
2. Why heat up the entire board? Won't that tend to undo stuff you've already flowed?
3. How do you do the 2-side boards? Again I see a risk of undoing some previously flowed work.
4. Can I use my Chicago-brand workshop heat gun? It has a 3/4" nozzle attachment and two heat settings 600 and 1000 watts. Heats stuff up pretty darn fast, but does create some breeze. Will that blow the parts off the board?
5. Can someone recommend a good website for ordering the solder paste?

Thanks for your help,
72

I will try to answer in line below:

--- John <af4ex.radio@...> wrote:

> 1. Why do we need the hot-plate? Doesn't the hot-air
> gun put out
> enough heat by itself to quickly heat up a local
> area and flow the
> solder?

To follow the recommended temperature profile of the
solder. Although it is not strictly necessary as I
have done some smt work with just the hot air gun.

> 2. Why heat up the entire board? Won't that tend to
> undo stuff
> you've already flowed?

Surface tension will keep the stuff already soldered
in place.

> 3. How do you do the 2-side boards? Again I see a
> risk of undoing
> some previously flowed work.

I place an entire side at a time and flow the entire
board side at the same time. Then flip the board and
place and reflow the other side later.

> 4. Can I use my Chicago-brand workshop heat gun? It
> has a 3/4"
> nozzle attachment and two heat settings 600 and 1000
> watts. Heats
> stuff up pretty darn fast, but does create some
> breeze. Will that
> blow the parts off the board?

I used an Uchida embossing gun (from Michael's Craft
store) and old souce pan on the stove. Kept the nozzle
about 3 inches from the board and only had two of the
0603 resisters move on me. Fixed them with a fine
tipped iron.

> 5. Can someone recommend a good website for ordering
> the solder
> paste?

http://www.zianet.com/erg/ShopSolderPaste.html

1 - $5.00 amount will allow you to do 2 or 3 ATS3B's.

Good luck,

-mike/w1mt

From: Garry
Topic: 1928 Message: 1930

John. I just recently started work on mine and found the same thing as you. I think I spent 3 hours and got 5 capacitors soldered in place. I chased those little things all over the board with the soldering iron. Either they stuck to the iron or I trembled and pushed the dang things off the pad when I approached the component. But the heat gun makes all the difference and the solder paste seems to hold the part in place in spite of the airflow.

I havn't been using the warming pad but it seems to me that anyone with an electric range could simply lay a piece of 1/4 steel or heavy aluminum on top of the burner and adjust the burner temperature to accomplish the same thing as the pot warmer.

Once the component has been soldered in place I have had no issues when flipping over the board to do the other side. I suspect that the heat does not penetrate the board quickly enough to affect the components that are on the bottom and even if the solder should get hot enough to melt, the surface tension of the solder will hold it. After all they can't wiegh much more than a flea. HI HI.

I have all the "fleas" soldered now, just have to do the solid state stuff and then the through hole and other miscellaneous as well as the filter boards. I don't know if that method is recommended or not but I just didn't feel I could chance trying to populate the entire board (one side) at once. If you should happen to twitch or stumble you could knock a few of the unsoldered items loose and the thing that struck me was how would I ever distinguish between capacitor values as I don't think they have any markings and they won't fit in my meter to measure them.

Anyhow you will find it a different story once you try that method. I believe just about everyone is getting their solder paste from Cash Olsen and that will be the link already provided.

Good luck

1931. Removing enamel from wire for toroids

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-10-30 04:59:27 UTC
From: km5ty
Topic: 1931 Message: 1931

I've finished by rig check out up to the filters. Everything went well. I built the ATS-3B under
a microscope and that made checking each solder connection very easy. I'm also a fan of the liquid flux for the SMT ICs, the trick is not to use too much and clean it regularly with alcohol.

I'm not sure if I have the toroids soldered in well. I tried to removeth enamel from the wire
using my soldering iron, and it was definately messy. Does anyone have a trick other than a solder pot?

Thanks,

Gary KM5TY

Thanks Garry, and Michael, for the advice. I just ordered me some solder paste and will attempt the hot-air method. I plan to use my Chicago heat gun set at 600F and see if it that works by itself, without a hot plate (with a safety net behind the work to catch parts if they fly off :-)

If that doesn't work then I'll get one of those embossing pens from Michael's and a cup warmer from Walgreen.

I'll keep you all posted on the results. Really looking forward to trying out the digital modes with the PocketDigi!

"doofus"? Hmm, never heard of that. Just did a Google and found this article by AL7FS, who apparently built one of these for his ATS-2: http://www.al7fs.us/AL7FS5ATSprint2.html

Is this the typical setup?

Looks like you still have to use a soldering iron, but keeps the pieces in place etc.

I'm going to try the hot air first.

John :

For what it's worth .. I just finished building an ATS3A using a soldering iron. I actually found the caps and resistors trickier than the ICs to install as they are so darned small. Some of the tricks I used were a bit of beeswax on the tip of a toothpick (Steve's idea) to move the parts around. I tinned one pad and I used tweezers to steady the part on the board while I reflowed the solder to tack down one side for starters, soldered the opposite pad then touched up the tinned pad. I used a magnifying lamp and built the rig inside a box lid that was about 2 inches deep to keep parts from flying around. I also highly recommend the suggestion of removing only a single part from the carrier at a time. The rig worked first time .. no issues. The trick to using tweezers is to use a very light touch so as to avoid flinging the part across the room at high speed; never to be seen again.

In advance I bought the smallest tip I could find for my Weller soldering station and very fine tipped tweezers.

Michael VE3WMB

P.S. I also tried AE5X's idea of taking an extreme closeup shot of the DDS chip using a digital camera after I soldered the chip to the board. When I uploaded it to my computer I was able to zoom in and visually check the solder connections on all of the pins. Worked like a charm.

Michael,
My 15-minute struggle with a single "741" resistor convinced me that
I'll never get this beast built with a soldering iron. I got it
soldered, but it was really blobby and messy looking.
The flow methods seem to promise an easier and speedier result.
Tnx,

I've found that breaking the surface of the enamel with a bit of sandpaper really makes "solder blob" stripping and tinning much faster.

Rip off about 2sqin of medium grit sandpaper and fold over to pinch the wire in between. Make one or two pinched swipes of the wire to be tinned just to break the surface of the enamel. No need to take it all off. Takes a whole 5 seconds.

Now do the solder blob tinning and it will go much faster than if the enamel was unscuffed.

John.

Just a tip for you that might be workable as it was for me. I am doing my build in an aluminum roasting pan (a very cheap thing made of extremely light aluminum). I picked it up at the local Dollar store for a couple of bucks. It has sides about 3 - 3 1/2" high and it has already saved me the loss of a component or two. What I like about it is that it is just so easy to clip an aligator lead to the aluminum and then run a wire from the lead to ground to give me a grounded work surface. Who knows, I could even use it to roast a turkey or something when I finish the ATS3B, that is if I knew how to do that.

I'm watching the list for this issue. By provenance, some funds have
been freed for the acquisition of a palm device at Chez 7J1AWL.
Could some on the list chime in with what specific device you are
using and what you like/dislike about it?

Mine is the Toshiba Pocket PC using windows 2002. I have heard that win2003 is much better but I cannot upgrade this machine to that so cannot confirm. Regardless, this machine does an amazing job with Pocketdigi. I was suitably impressed with the software. I have not used it to transmit yet (so don't know what issues I may find there) but it sure receives just great.

Garry, down here in Florida (EL98) we don't worry much about static electricity. Very high humidity most of the time.
For organizing my work area I use those carboard shells from the 24-can soda pop cases: one to hold the parts dishes and another for the soldering work and tools. But I'm worried that my heat gun will blow the parts off the board, so I'm scouting around for some kind of netting for a backdrop.

1951. SMT

Yahoo group: AT_Sprint (2002 — 2008)

From: sm0xg
Topic: 1951 Message: 1951

I have now finished the soldering on the main board but not yet installed L3.

I am now 77 and have to use +4 reading glasses. I used a 200-dollar hobby binocular microscope on which I mounted a plastic tray with walls and did all the soldering with a thin tipped iron in the way Steve recommended. Only tools a finger nail to hold down and a pocket knife to put each part in position. I used a thinner solder 34 SWG .23 mm so for each solder point I had to feed a sizeable length of solder and under the microscope you can clearly see what happens. I newer had to use the solder wick. Garry's tip on using an aluminum roasting pan seems right.

So bad eyesight should not prevent us from playing with SMT!

I believe it is the E740. (can't see anything on to tell me) I have had it for about three years, bought it used from a friend and seldom ever use it except to play solitaire and read the odd E-book. Until Pocket digi that is.

I also have a very nifty little folding keyboard for it that opens to approximate the size of a laptop keyboard which will be very handy for PSK and other digital modes.

I just soldered the less-populated side of the ATS-3B board using Cash Olson solder paste, candle warmer/heat spreader, and embossing hot air tool. It went perfectly. It took me over an hour to identify and place the parts - I even measured some of them to be sure what they were. The 0603's looked terrible prior to heating, crooked and smeared with paste, but then they just popped into place when the solder liquified. This is the most amazing thing to see!

I think that a 600 watt heat gun may be too serious, but it may work as long as you don't get too close or go too fast. It's too much heat and too much air if you get too close. The key to the hot air method is to get just enough heat underneath, and then add just enough heat above, without the temperature going too high and ruining the board or the parts. The 320 watt embossing tools have just enough heat and just enough airflow without either being too strong. The result is that you can get pretty close to the reflow temperature profile recommended by the component manufacturers.

You start with the hot air tool about 3 or 4 inches above the preheated board. You take your time and bring the tool closer and closer, while moving it gently around a zone of the board. You end up about 1-1/2 inches from the board, still moving, and the paste melts - you give it some time, maybe 10 or 15 seconds, to be sure it's all melted - then you move over a bit, and that zone melts pretty fast, because it's been getting hot air. Once you've melted the whole area, just back the nozzle away to 4 inches, and keep it moving - you're lowering the temperature gradually, like the profiles in the data books. You just gradually move it away for a minute or two, then turn off the tool, and after another minute or so remove the board from the preheater (candle warmer/heat spreader).

As others have said, once you do this, you will be changed forever. I think now that we all can do 0603's if we can get the paste mostly on the pad and get the part reasonably close to where it belongs. The amount of paste is small but very non-critical - and you don't need near the accuracy of positioning what you do when you solder the ends one at a time. The paste doesn't hold the parts tightly, but it's has enough hold that they don't jostle while you're positioning the other parts, as long as you don't touch them. The easiest parts are those little 3-legged devices - they just position themselves perfectly.

Now I have to start the busy side of the board...

Sounds like magic! Certainly sends the message that hot-air is the way to go (though my hat's off to SM0XG and the others who have succeeded with the soldering iron).

W1MT answered my question about the need for pre-heating, which prompted me to do some further research. Here's a nice Wikipedia article which further helped me understand why it's necessary to slowly heat up the work:
http://en.wikipedia.org/wiki/Reflow_soldering
<http://en.wikipedia.org/wiki/Reflow_soldering>

Also the place where I ordered the solder paste has a good writeup on this too:

http://www.zianet.com/erg/R276.pdf <http://www.zianet.com/erg/R276.pdf>

I'm still planning to use my Chicago heat-gun (which can put out 630F-1000F degrees, not watts as I previously wrote) (You can get these at Harbor Freight for $10, when they're on sale:
http://www.harborfreight.com/cpi/ctaf/displayitem.taf?Itemnumber=35776
<http://www.harborfreight.com/cpi/ctaf/displayitem.taf?Itemnumber=35776>
) I've got attachment set which will narrow the nozzle to 3/4".

My original thinking was that I should apply "max heat" quickly, melt the solder and get out as quick as possible to avoid heating up other stuff. I now realize that this is TOTALLY WRONG and will create thermal stress which can do a lot of damage.

The correct way (according to Kester) seems to require allowing at least 3-4 minutes of slow heating to bring everything up to a max of 225C (437F), at which point the magic described above should happen.

So I went to Harbor Freight yesterday and bought me a Centech infrared laser thermometer (Not exactly cheap, I paid $59 for this thing, but you can find them cheaper on line:
http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=170141763311
<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=170141763311>),
which can read up to 1000F within a degree or so. Has a nice flexible head which can be pointed very precisely with the help of an on-board spotting laser. I don't have the solder paste yet, but I tried heating up the board and held the heat gun back far enough so that I could watch

the on-board temperature rise up to about 400F. Really an amazing
gadget!

Starting to feel a bit more confident about SMT now (and not worried
about blowing parts away anymore, hi)

Just noticed a faint resemblance of KX0R's "verses" above to Carl Sandburg's poem "POOL" (which KX0R has likely never seen). Carey is a fine poet!

POOL
Out of the fire
Came a man sunken
To less than cinders,
A tea-cup of ashes or so.
And I,
The gold in the house,
Writhed into a stiff pool.

-AF4EX

--- In AT_Sprint@yahoogroups.com, "John" <af4ex.radio@...> wrote:

John,

The Wikipedia article is great, and it agrees with all the stuff I've ever read in data sheets for components, etc. When we use the candle warmers, hot plates, or frying pans, we're doing the preheat and maybe part of the soak. The hot air can be started from some distance out, so we bring up the temperature over several minutes, effectively completing the soak and going on into the peak reflow temperature.

I finished placing and soldering both sides of my ATS-3B board yeserday and last night, and it went real well. I essentially used the Cash Olson method, except that I modified a candle warmer as discussed in previous posts.

It turns out that the soldering is really easy using the embossing tool. I wasn't far from the thermal profile described in the article you suggested. There was no problem with components on the underside coming loose or moving, because I used pennies to lift the board slightly off the hot heat-spreader surface. I'm running my candle warmer on about 140 VAC, and the heat spreader (aluminum surface, 1/4" thick) is hot enough that water drops dance on the surface as they boil. So there is a nice preheat - I get the candle warmer and spreader hot first; this takes almost an hour; I put the board on the surface and let it sit for about 5 minutes; then I bring in the hot air tool (320W embossing tool) and let it bring the temperature up from 4 or 5 inches away, while keeping it moving. This is the soak - the solder doesn't melt, but the appearance of the paste changes. The Wikipedia article tells what's going on with the solvents and flux during this time. We bring the hot air tool very gradually closer, and we avoid thermal shock. Then the solder melts when we get to the required temperature, and we keep it there for a little while to make sure the hidden areas and thicker metal leads get hot enough to flow. Once all parts of the board are soldered, we gradually move the nozzle higher and higher, keeping it moving, very slowly letting the temperature go down slowly. The last step is to remove the board from the hot plate.

All that stuff is easy. What is hard is actually placing all the components on the busy (dense) side of the board without knocking some of them out of place while you add more and more parts. The solder paste helps to keep them in place, but it seems to dry out or become less tacky after a couple of hours - maybe it has something to do with the altitude and low humidity here in Colorado. By the time

I had all the parts identified and placed, I was getting a little freaked. After all, it was midnight and Halloween.

It's all or nothing, because once all those unmarked capacitors are placed on the paste, if you get tired and have a little accident, say you just brush the board with a sleeve or a tool, you could lose all your work! Then you'd have a horrible puzzle trying to identify a whole buch of unmarked parts all smeared with solder paste! Those of you who have done this know what I mean. You want to do the whole side of the board and get everything soldered, because you don't dare have an accident.

Others have suggested putting the parts on in groups, and this is a possibility, even though it means remelting some of them. The semiconductors are the most fragile, so they should be in the last group, if you try this.

The semiconductors weren't too bad. The AD9834 was a challenge to get lined up - I tacked down two corners and then laid thin "ropes" of paste down each side, right where the leads meet the pads. I only had a couple of little bridges to remove with braid afterwards.

I mounted some of the 8-pin IC's with just paste, but of course I ended up bumping one of them and having to re-do it prior to reflow. I bumped several caps and resistors off their pads, and R1 either got up and walked away, because I never saw it again - or else the Halloween ghosts got it. It just disappeared...gone.

It was real nice to see all those messy little blobs of solder paste turn into nice solder joints when the hot air did the job later. I only had a few spots to touch up - all due to excess or sloppy paste.

The one-part-at-a-time manual soldering method is safer and less stressful than placing one whole side of the board at one time and reflowing it, because your losses are always limited, and you know you're going to get there without a big crisis.

Safer? Consider this - what is the thermal profile of a component that you solder down manually with a hot tip, first one end, then the other. There is an enormous thermal gradient across the tiny part. The capacitors contain microscopic layers of ceramic dielectric, and those layers can crack due to thermal stresses - this is in data books from the capacitor companies. The reliability of the parts may be reduced by thermal shock, even if failure doesn't occur immediately. I worked for a company that had a major reliability problem with chip caps caused by the soldering methods used...we all got educated on thermal profiles and soldering methods.

What saves us is that today's components have been improved for many years, and they can take a lot of abuse. Nevertheless, the hot air methods offer a much better thermal profile than hand soldering. When you touch a hot tip to one end of an 0805 part, that material

goes from about 70F to maybe 700F in less than a second - and the heat has a steep gradient across a very short distance to the other end of the part, which is surely cooler, and may even be already soldered down, in which case it's attached to a heat sink! This increases the gradient even more! Those parts like being brought up to temperature gradually and uniformly, even though they stay hot longer, with the hot air. Also their peak temperature should be much lower than what you give them with a hot iron tip, if you don't use the hot air correctly.

I'll post a photo of my soldered board in the files later tonight. It looks pretty good. I can't say the board works yet though - I just mounted the through-hole parts earlier, and now I want to get outside and forget all these little parts for a while.

The solder paste method is not for everyone...but it works for this kit. If you have any plan to try this, I suggest ordering a Norcal Dummy Load - it's a great practice kit for surface mount - before launching into the ATS-3B:

http://www.norcalqrp.org/ncdummyload.htm

Good luck!

Carey,
Good write-up. Sounds like either method, solder-iron or reflow,
requires some skill and lots of patience. Good luck on the rest of
the build, hopefully you're be hearing the Morse "8" soon.

I was hoping my solder paster would arrive in the mail today, but no
luck.

From: Randal
Topic: 1960 Message: 1960

I had such a good time building my ATS3-B I couldn't bring myself to hide it in an Altoids tin. So, found a small parts box that didn't have a designated function and stuffed my ATS3-B in there. Now while snooping around the bands I can look at all of those TINY components and remember why I bought a stereo-microscope. Man dose that help these 60 something eyeballs.

This rig is a ton of fun. Making contacts left and right, my KX1 is just sitting on the shelf.

1962. Kester Solder Paster- How Old Can You Go?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-05 17:57:29 UTC
From: wi1p@arrl.net
Topic: 1962 Message: 1962

Hello Sprint SMT Guru's,

In my endeavor to get the necessary materials ready for my ATS-3B assembly I have obtained two syringes of OLD, 3 plus years old, Kester solder paste.

The details on the plastic solder paste syringe labels are as follows:

Kester Puremark 202,
Net weight 100 G, Alloy 63/37 85%
MESH -325+500 Lot # 4053021
DOM 05/18/04 VISC. PS.

Kester TYPE 256HA
Net Weight 100G Alloy 63/37 86%
Mesh -325+500 LOT # 4052048
DOM 05/13/04 VISC. PS.

My questions are;

1. Are these too old for use manually in the candle warmer / embossing tool solder flow technique?
2. How old IS too old for this stuff to still be usable?
3. Which is better for this type of application, the 202 or the 256? They both look the same to me.
4. Should I do anything to the paste to make it more flow able or workable if it is usable?
5. Would you recommend buying new stuff to avoid ruining a good project?

Thanks in advance for any assistance.

There's nothing that goes "bad" per se, but over a period
of time the lead granules will settle out of the flux/carrier
goop. Depending on how much trouble you want to go through
to resurrect it, you could take it out of their syringes,
warm it up in a suitable mixing vessel and mix it up again.
I keep mine in small glass vials for this very reason. I
dab it on the various pads using the stick from a bench swab.

1966. Finished LAST band module

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-05 20:22:25 UTC
From: john
Topic: 1966 Message: 1966

What a patience test building the band modules was for me. Fortunately I started with the hard one (the 80m) first. Using a headset magnifier sure helps in keeping things under control.

Made a good number of Sweepstakes Q's over the weekend, but was hampered by a bout of the flu, so my time was limited. I was very impressed how well the rig did.

Now to get it home in the tin I found. Looks like I'll be able to include the board plus the full compliment of band modules in this particular tin (a tin that a wallet came in).

Thanks for the fun kit Steve!

Hi Jess,
I agree...give it a shot! If you have a good desk magnifier, a soldering iron with a small tip, GOOD tweezers, solder wick, and patience you'll get it done. It goes pretty quickly once you get the hang of it. I'd done a few very minor SMT pieces prior to this, but this was my first significant SMT project.

Apart from losing a couple parts to the Rug Monster, it all went well, and the rig works FB on all bands (Just worked CO8LY on 17m).

Try it...it's just one piece after another!

Hi
Like you I had doubts whether I could build this kit. My background experience includes building a range of add-ons, a home brew synthesised all band QRP TX/RX about 23 years ago and last year, a Small wonder 40m QRP TX/RX. None of these had surface mount devices! Through this site I have picked up lots of tips and finally took the plunge and bought the kit. Here are some comments:
* The rig is up and running on all bands and is an amazing kit
* My eyesight is not wonderful, so I bought a head mounted 3Dmagnifier which comes into use by tilting my head down a degree or two when needed. This together with hand lens to read component values worked really well
* I was attracted by the reflow hot air method, but eventually decided to stick to my thermostatically controlled Weller WHS 40 D soldering iron and soldered parts direct. This worked well and the only problem I encountered was surface mount devices sticking to the end of the iron a couple of occasions. Eventually I used my finger nail to hold them in place while I tacked one end.
* Work in a metal tray. Mine is stainless steel with sides about 2 inches high. It saved me losing parts on a couple of occasions, and had a well round the inside for collecting the fat which was a good place to park the packaged components until needed.
* Some of the resistors are tiny - I dropped one in the tray and was convinced I had lost it, but eventually tracked it down. No chance if it had dropped on the floor or the work bench.
* I worked very slowly and checked every component after soldering with the head magnifier plus hand lens.
* I bought some very fine desoldering braid to remove bridges on the tiny ICs.
* Before I started, I got an old PC board, removed some of surface mount devices, cleaned up the pads and then resoldered them. This was really good practice for someone new to these devices.
* The kit is really well designed. I liked the board mounted sockets which meant that during the setting up phase I wasn't dealing with the normal birds nest of temporary connections; just a temporary antenna connections.
* The RCA antenna socket kept working loose until I added an anti shake washer

So, my advice is go ahead and build the kit, but take your time. Having got it all boxed up I am now looking forward to a winter of QRP on 6 bands!

http://ph.groups.yahoo.com/group/AT_Sprint/photos/view/e6e8?b=5&m=f&o=0
Nice idea. I have had my band modules kind of kicking around--and
they're not all that sturdy for jarring so much. A simple breadboard
and socket arrangement may be coming up for me, too.
Thanks for the tip.
It's a shame the photo section of this yahoogroup doesn't allow
commenting or notes.

Well, I have started looking at upgrading to a nicer multimeter. I have been using a small, cheap one--basically a glorified battery tester, for too long. I notice several models packed with features under 200$--even many in the 35$ range that I might enjoy years of gentle use from. What do y'all use on your bench? Anything to avoid? Thanks in advance for your replies.

1973. LED Flashlight

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-06 03:24:24 UTC
From: John Paul
Topic: 1973 Message: 1973

Guys:

I don't usually brag about a product.

I bought a LED flashlight several years ago for FD and we went up to
Black Balsam, Sam's Knob, on the Blue Ridge Parkway in NC. I took the new
LED flashlight and loved it. I hiked with it in the dark, I hung it from
the
inside of my tent and used it all night to read and see my rig with. I have
used it for several outings since then and had it for my personal use too,
for things around the house and for night fishing on the pier and cooking
on the grill. It has worked through thick and thin in the rain, and in the
cold and in the freezing weather.

Well, two weeks ago I participated in the ARCI contest and the thing
finally gave up the ghost and quit. I had to revert to another light and
found that this one was really missed.

I sent it off to the manufacturer last Tuesday. I got it back today.
The bill, NOTHING! Less than a week away and fixed.
They fixed it and put WARRANTY on the bill.

I mean this was four years ago.

Streamlight, in Pennsylvania, fixed it for free and then paid the
postage back to the house.

I put a note in the box when I sent it last week and gave my
email address to tell me how much to send to get it fixed.
I did not get an email reply. I got the flashlight back, fixed.

It is the Yellow, 4AA, 7 LED, light.

Now it is working like new and I am, yes, bragging about
their service.

>I bought a LED flashlight several years ago for FD and we went up to
>(snip)
>I sent it off to the manufacturer last Tuesday. I got it back today.

Apparently there's a bit of this going around. A couple years ago the very first LED flashlight I ever bought some four or five years previous at a flea market developed two problems: an intermittent switch and the silvery stuff flaking off the reflector.

I had seen at Canadian Tire the flashlight was still being sold by Dorcy, and had a lifetime warranty, so I emailed them in Ohio I think and asked what to do. They emailed me back within hours and said just send it in. Which I did and less than a week later I get back a brand new flashlight with a set of batteries. No charge.

This is, as you found, extremely good service for a commodity item worth less than $15. It's also a yellow, 4AA light.

It's great that some companies realize that keeping an existing customer happy makes much more sense than antagonizing someone who cares enough to actually want to use their product.

It's still working fine, btw, and the new flashlight, although identical in appearance, has a much brighter LED.

I dont think you can go wrong with any kind of Fluke meter. Many nice features, many of which are aimed at meter protection from mis-application. (Try measuring line voltage on the resistance scale of one of the Harbor Freight meters... you'll see what I mean :-)). Sooner or later you WILL do something like this , and when you do, you'll be glad you have a quality meter.

OTOH, the HF meters make great, cheap panel meters for Power Supplies (they were 2.99$ last month on sale).

1976. Muscle or human energy?

From: tf3kx
Topic: 1976 Message: 1976

I am interested in operating my QRP rig, such as an ATS-3, solely on muscle power, that is, only running it with energy that I have produced with my own physical work (may be stored and buffered in a battery)! Are there any suggestions or links on where I can find equipment for this or information?

A couple of additional questions right away...

- Are there any PORTABLE electrical generators available?
- What kind of rechargable batteries would you suggest?

Look at the hand generators used for backup for weather radios, etc.
Also, there are ads for a cycle powered kids video game which is
advertising that "the more you pedal, the longer you can play the game.)

Many years ago during field day two of us hooked two bicycle generators
in series, put a few hundred thousand micro farads of capacitance across
them to store the energy of the pedaling, ran a 12 VDC regulator off it,
and powered a 1 watt VHF transceiver for long enough to make 5 Q's for
the "alternative power" bonus.

I'd say that with current technology you should be able to find many
hand or pedal powered generators with sufficient capacity to run a QRP rig.

I did a Google search for "Hand Powered Generators" and the first thing
which came up was http://www.los-gatos.ca.us/davidbu/pedgen.html

That, and other Google references, might give you some good ideas.

As for batteries, Lithium Polymer batteries are very good, but if money
is a concern, Nickel-Metal Hydride is a good choice.

2 or 3 lithium LiPo or LiIon cells will run this rig for a long or longer time, depending on the mAH rating.

I think that for portable work batteries are lighter and more reliable than any kind of muscle power conversion device you're likely to come up with for a reasonable cost. Even a bike generator weighs more than three 18650 LiIon cells, or similar LiPo cells, and those 3 cells will give you 4 or 5 watts of RF and many hours of casual operating. Similar results happen with NiMH cells - they just weigh more, and you need more cells. The ATS rigs are incredibly efficient on battery power.

With any kind of direct mechanical generator you have the problem of voltage regulation and perhaps storage - generators generally require magnets, coils, etc., and these parts are heavy. On the other hand, solar power combined with battery storage makes a lot of sense for this radio - a small panel rated for a watt or two would do the job of collecting enough energy to charge your battery - and the weight isn't bad.

If you don't care about cost, there may be small wind generators available for emergency power. One of those might provide a starting point for direct human power.

It would be hard to operate this rig and send CW while cranking anything, unless you're actually on a bike already...but as those of us who ride real bikes a lot know, bike generators are a real drag, and even on a bike it's more practical to carry storage batteries to run lights. The riders with the big HID lights are using lithium packs.

Jess,

Most of us here are going to tell you to go for it, if you can figure out how to see the parts, and if you can handle them. Practice makes perfect, or at least good enough. I like high-power reading glasses and a stronger hand magnifier for inspection work. You should plan on spending significant time inspecting your work.

By all means order a Norcal SMT Dummy Load and/or some Tuner Uppers - these are useful, easy, low-cost, surface-mount projects that will give you practice and confidence. The Dummy Load provides a convenient way to measure QRP RF power and to check any other wattmeters you may have.

I don't recommend the hot air method as a first-time surface mount way to go. I did my ATS-3A with hand soldering every joint, and I just finished the 3B using the Cash Olson hot air method. Placing the parts with solder paste requires considerable control and patience, it's an all-or-nothing game until you see everything melt. You have to be incredibly careful not to mess up the placement of all the parts as you add more and more parts. The ATS-3B is pretty dense on one side. I would do the paste method again though. The big advantage of the one-part-at-a-time soldering is that you can do just a few at a time, not get too stressed, and take your time until you get rolling.

This is one of the most satisfying kits ever produced. Once you get the rig running, it's nothing short of miraculous. You will be as proud of yourself and what you have learned as you will be impressed with all the hard work that has gone into the design, the upgrades, and the firmware.

Last night I had a 25 minute ragchew on 40M with a station in VA, and he it seemed like it went well for the other guy as well as me...otherwise it would have been over sooner. I don't even have the 3B in a case yet. Amazing.

If you get it outdoors, into the field, you have another set of thrills coming. When the sunspots return, we're all going to be amazed at what these radios will do.

Practice and then go for it.

1981. 150 pF Caps in the Crystal Filter

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-07 05:56:20 UTC
From: radio_kx0r
Topic: 1981 Message: 1981

This is really a public question for Steve Weber - I figured a few others might be interested in the answer:

I noticed that the ATS-3B uses three 150 pF capacitors in the crystal filter. I believe the ATS-3A used three 100 pF caps in the same places.

What is the reason for the change, and what are the tradeoffs?

My rig is running now, and I just went through the alignment carefully. I used a scope. When I centered the filter bandpass, I found that my filter has a symmetric double peak, with slightly less sensitivity in the center zone than at the two peaks. The peaks are about 12 to 14 button clicks apart. We're talking a db or so here.

Once the alignment is done, the filter sounds nice in use - I hear no double peak when tuning - the overall receiver passband is narrow, just a few clicks, and the skirts are steep and deep. Unless I make measurements - haven't yet - I'm not sure how this filter compares with the one in my 3A. Both are good. I can hear signals at 0.2 uV with either radio.

Why did the filter change?

Thanks

Interesting question...

I did the calibration last weekend, and also noticed the 2 peaks over abt 12 clicks.
(didn't gave it much thoughts at the time, but going through my notes I saw I had 25 clicks on the 3A)
If the rate hasn't changed (1click = 10Hz on the 3A) this should mean the 3B's filter is half as wide as the one on the 3A... if the skirts have remained the same. but this is only a guess of my part, one should measure/calculate (or wait for an answer from Steve ;-)

Jess,
KX0R and others may not recommend it for self-identified newbs as yourself--but I am a relative newbie myself and had a resoundingly positive experience with the hot air method.
My experience is only my own, and I certainly respect those of others on this project. For my part:

1. It wasn't all-at-once for me at all. You can reheat parts of the board, do one side at a time, even one component at a time using cheap and simple embossing tools. Less than 20 bucks, I mean.

2. My experience with placing parts was a walk in the park. Easy and fun. Any mistakes were simply a matter of wiping off the part and moving it. Even a flipped part AFTER using the air gun and allowing the board to cool was a cinch with a tweezers and a conical air-focussing tip I made from a beer can and scissors.

Skid on in to my photo set if that benefits your process:
http://www.flickr.com/photos/jonathancharles/sets/72157602077258104/

Again, I do not have as much experience in the hobby as many of the more experienced hams who have endorsed the tried-and-true soldering method with a fine-tipped iron. I built the QBSA that way and didn't find it easy. Messes were very hard to extricate myself from--and it still doesn't work right. I wish I had simply air gunned it.

Best of luck with my 2 cents' worth.
Best 73,
Jonathan KC7FYS/7J1AWL

1984. ATS-3B Power Output

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-07 07:49:48 UTC
From: radio_kx0r
Topic: 1984 Message: 1984

Getting 5 watts out of the ATS-3B on several bands is easy, but doing this creates some new issues. So I'm going to tell everyone what I've learned so far, so you'll know what you're in for if you try to max out this radio. First read what Steve says in the manual. He's right about everything related to this topic.

I'll just summarize what I've learned and then post more details as a Word document in the Files section. Those of you who are risk-takers or worse can read the rest there.

When I ran 12.0 volts into my ATS-3B, I was able to get just over 5 watts on 80, 40, 30, and 20M. All I had to do on 80, 30, and 20 was adjust the separation of the turns of LF1 and LF2. On 40M I increased C2F by 150 pF and also adjusted LF1 and LF2. I used #26 wire instead of #30 wire for LF1 and LF2 on all modules except 80M, because it's easier to work with, and the Q is a bit higher. I wound all coils with the specified number of turns.

On 17M I'm getting 4.9W, and on 15M I have 4.8W with 12.0V. Once the band modules are adjusted, the current draw rises as you go up in frequency, from .64A key-down on 80M, up to .81A on 15M.

With a 9.0 volt supply, I get 2.8 to 2.9 watts on all bands, with the current increasing from .48A to .58A from 80M to 15M.

With 6.0V, it's 1.2 to 1.3 watts on all bands, and the current runs from .32A up to .40A as the frequency is increased.

There is quite a range of adjustment possible, and getting 4.5W at 12.0V should be easy.

If you go for 5W, your rig will be pushing the current limit - 0.82A - at which the rig trips. All my measurements were into a known good dummy load, and since I want to run into a BLT, I knew that the rig would see some mismatch even at the "Tune" setting of the BLT. Using a 9V supply, the current draw varies about 10 or 15% above or below the normal value when you tune the BLT for a match; this corresponds to an SWR of about 1.4. So you can't adjust a BLT for a match without tripping the rig off, particularly when operating on the higher frequencies and using more than a 10V supply.

You can change the current limit easily; 5.6K in parallel with 680 ohm R47 will permit about 0.9A to flow before overcurrent trip occurs. This might be enough to avoid nuisance tripping when tuning and still have protection when something worse occurs. I think raising the current limit above 1A would be foolish - the limit is there for a reason, and you shouldn't mess with it unless you need a

little extra and understand the risk. Others have suggested tuning the rig up with a low supply voltage, and then kicking it up for operation, but I think you'll need to raise the current limit just to operate reliably with a 12V supply. You'll never be able to tune through a T1 autotuner at full power with the 0.82A limit...I'm not sure that's a good idea anyhow.

This transmitter seems strong and efficient. I did a tough test on every band - running with a 7.5V supply, I operated the rig into reactive mismatches - SWR's of 2:1 or even 3:1 - by mistuning my BLT in the "operate" position. I watched the output on a spectrum analyzer, and I never saw an instability or a parasitic oscillation. The 0.82A current limit didn't trip, but it would have at a higher supply voltage.

On all bands, including the 21 MHz "worst case", with 12V and key-down operation for many seconds, nothing in the radio is getting hot. The 2N7000 mosfets are just warm, and not nearly as warm as the ones in my AST-3A running on 14 Mhz. The little 74AC02 driver IC is getting warm, because it's doing such a great job driving the gates of the final mosfets. The efficiency of the ATS-3B at 21 Mhz is as high as that of the ATS-3A at 14 Mhz, probably because the new driver IC works better. On the lower frequencies you can hardly tell that the transmitter has been on, even after many seconds of key-down at full power....everything is just slightly warm.

The only thing I've found to worry about is the voltage swing on the final mosfet drains. For some reason I'm seeing 50V p-p on 17 and 15M, but only 30 to 40V p-p on the lower frequencies. I found that I had to use a very short 2 cm ground on the scope probe to have any confidence in this measurement. Steve mentions this voltage swing in the manual, and it's good that zener D4 is there - I think you really need this diode if you plan to run the rig on 12V. I may be imagining it, but I think my D4 is getting a bit warm on 15M at full power - just enough to feel after keying for a few seconds.

The PA seems more robust and more efficient than what we had in the ATS-3A. The increased gate drive and the current limit protection are great improvements. I think this final should be fine for sustained digital operation with a 9V supply.

The keying shaping has been greatly improved compared to the previous version. The rise and fall times are 2 to 2.5 mS, and they don't change much as the supply voltage varies from 5.5V to 12.0V. The keying sounds solid, fairly hard, but the signal is free of significant clicks. The new keying circuit is simple and effective - thanks Steve!

I'll write some more details and post in the FILES section soon, but this is the main stuff.

Boy am I amazed and delighted with this rig!

1985. Muscle or human energy? - Clarification

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-07 13:11:52 UTC
From: tf3kx
Topic: 1976 Message: 1985

I get the point - batteries are much easier to handle and travel with
than a mechanical generator.

My idea is, however, to start my own challenge where I would
accumulate QSO's that are made totally with my own energy - as an
alternative to solar, wind or commercial energy. Now, that means I
could for that matter charge up efficient batteries, such as LiPo,
using some mechanical charger at home or on a bike, and then tap this
energy off the batteries while operating. Starting with discharged
batteries, I could charge them up to a useful level and from then on
claim that I made all those contacts, across countries and
continents, with my own muscle power!

So I would need a suitable generator(s). Portability would be nice,
but is not a top priority. Then I would need batteries that are well
suited to be charged up with such generators. If the generator
voltage output is highly variable, and the duration of charging
sessions may vary - possibly only a few minutes at a time, I would
need batteries that are well suited for this.

wrote:

Jess,

With that many rigs built, the ATS should go together pretty well.
The component count isn't huge, and the only problem is that the
parts are tiny.

I use the OHR WM-2 wattmeter. It is pleasant to use. I calibrated
mine against several schottky diode detectors connected to known good
50 ohm loads. That's essentially how the Norcal load works - it's an
accurate 50 ohm load with a SMT schottky detector built in; you just
attach a DVM and read your power off a graph. Cheap and reasonably
accurate. For a few bucks, it's a great surface mount practice kit,
whether you need it or not, especially if you decide to try the hot
air reflow we're buzzing about.

I think you may have to go to one of the professional HP RF power
meters if you want more accuracy. Or just use a scope and your dummy
load, if you can verify the calibration at RF. Whatever method you
use, verify that your load is REALLY 50 ohms resistive at the
frequency you're working with. This includes any cables, adapters,
etc. I use an MFJ-259 analyzer for this, and it has revealed many
small errors I was previously unaware of. Many loads have an RF
error of 10% or more if measured with cables.

The manual for the ATS-3B was in the "FILES" section of this group
site last time I looked.

Good luck

Kristinn,

OK, if you're going to charge your batteries with human power at home, I suggest you get an old bicycle, mount it rigidly so it's stationary, and figure out a way to connect a generator to the back wheel. A small automobile generator could be arranged to run off the back wheel with a belt, or even off the tire. You would ride this like an exercise bike - just make sure it's solid so you can put out your power safely.

Others have done this for Field Day. Some have kept stations on the air for hours. These were much larger rigs than the ATS.

If you're in pretty good shape, you may be able to generate 50 or even 100 watts. Professional cyclists can put out hundreds of watts for sustained periods. Even if you get only 10 watts, that would be enough to charge up your battery for lots of QSO's.

Proving that you generated most of the energy yourself is easy - just discharge the battery to its recommended low voltage point with a resistor. Lithium batteries should generally not go below 3.0V per cell. Other batteries have published specs. The charge with your personal power.

I picked up a small crank LED flashlight at Wal-Mart today ($9.95, made by Garrity - they have a web site, <www.garritylites.com>) One reason I got it was it had a DC output jack labled "5V". I found a plug for the jack and it puts out a little over 6 volts with no load. Starting with a 100 ohm load and working lower, I found it will produce about 5 V with a 22 ohm load, or an output current of about 220 ma. Not too bad. I think you could actually charge a battery in a reasonable amount of time with this. Or at least keep one topped off.

Of course, I had to take it apart. Not too hard to do, but there are a couple of hidden screws. Inside is a plastic gear box assembly connected to a small DC motor labled 6V. Its a type commonly found in CD players. There is also a small circuit board with a 1N4007 bridge rectifier off the motor, a small filter cap, a power transistor, a diode and a resistor. Also a 3.6V 80 mHr Ni-MH battery, two switches and the power jack. Looks like the power transistor drives the LED lamps.

This gizzmo might work out even better than the solar charger for keeping my PDA running on the trail. Espcially since I lost the solar charger! Put it on the roof of my car one afternoon, as it was in the sun. You can guess what happened later that evening....

Kristinn :

Freeplay has a hand generator that is designed to provide 14v of
charging capability, targetted mostly for Cellphones, Ipods etc.
This might meet your needs, see the link below:

http://www.freeplayenergy.com/products/portable-power/mobile/freecharge12v

Michael VE3WMB

P.S. I just bought one of their EyeMax Weather Band radios (AM/FM/Wx)
that has a built-in crank for charging as well as a small Solar Cell
and it even doubles as an LED flashlight! The Receiver works very well
and seems to be very well constructed.

Benny,

Today I measured the bandwidth of both the ATS-3A and the ATS-3B receivers. I did it this way:

Crystal oscillator source (Norcal Tuner-Upper), set of RF attenuators, HP400D AC VTVM connected to headphone jack; HP606A generator used to measure input levels.

Set the RF input at several levels near -90 dbm, stepped the receiver through a set of 50 Hz steps, and recorded the audio output of the receiver. I found that near -80 dbm, AGC is working, so the signal level must be set lower so that AGC effects don't change the curves. I got several sets of data and plotted the curves by hand. The resulting curves include both the IF selectivity of the crystal filter, plus the additional peaking from the audio section.

The bottom line is that both receivers have very similar selectivity curves. The -3db points are about 150 Hz apart. The -B looks a bit flatter and maybe a little wider than 150 Hz at -3B down. Both receivers have the -30 db points about 450 Hz apart. The curves are real pretty, almost symmetric, with no double peaks or other artifacts.

These receivers have ideal selectivity curves for CW operating with weak signals in the presence of stronger signals close by. They sound great, and I can't tell much difference between the two receivers when I listen to CW signals.

I have no way of measuring below about -40 db down from the peak, because the AGC action alters the curve when you run the input signal up; also you can't measure below a certain level due to the noise floor. Both receivers have a noise output of about 1 mV RMS using my setup, on 80M, with the inputs connected to 50 ohms.

The AGC action is very strong - the audio output of my ATS-3A is essentially flat - it doesn't increase - above about -82 dbm, with the signal in the center of the passband. My ATS-3B levels out at -85 dbm; it also measures 3 db more output than the ATS-3A, for the same input, when measured with lower-level signals. These measurements are for 40M.

I still hope Steve will comment of the 150 pF caps vs the older 100 pF caps in the crystal filters.

These are both excellent filters, and it's nice to see why the
receivers perform so well. Such nice performance from a few
inexpensive parts! Lots of good decisions here.

Basically, I thought the filter sounded a little too wide with 100p caps so
I used 150 to make it a little narrower.

1995. Tuner for 80m-15m?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-08 17:06:50 UTC
From: John
Topic: 1995 Message: 1995

[Still waiting for my solder paste, so reading up on antenna tuners].

Is there an "ideal" portable/QRP tuner for the ATS-3B that will
cover all six 3B bands and handle reasonably "random" antennas?

I have K0XR's writeup on the BLT, but am concerned that it does not
cover 80m and also seems to have problems with antennas far from
resonance. (I plan to use the tuner on balcony railings, downspouts,
etc that might be reactive).

If the BLT is redesigned to cover 80m will it still work for 15m?

I'd like to keep the balanced line output for running TV feedline to
a 40/80m loop antenna that I'm planning to build.

Has anybody tried the SLT with the 3B? Does it cover 80m and handle
random antennas well? (i.e. overcome the 3B's shutdown detector)

Another tuner I've read about is the ZM-4.
http://www.qrpproject.de/UK/ZM4UK.html ,but apparently not used
much. Has anyone tried this one?

Thanks for any feedback.

I've had fairly good luck with Steve's ALT design (same design in Doug's SLT) with an added inductor for 80m (just twice the highest value inductor as what is in the ALT). You can find the ALT design on Steve's site or the SLT manual from http://qrpkits.com/ .

I've not tried my end fed wire on 17m/15m yet, but once I complete my 3B, I'll build another ALT in a smaller and more friendly form factor and try out different lengths. I "may" also try to build another Fuchs tuner as well, but I'm kinda gun shy as my first attempt wasn't very successful.

There is no "ideal" antenna coupler. For QRP operation, one needs to look at tradeoffs of size, weight, and losses in the inductors which are used. In the olden daze, before microminiaturization became "the rage" - folks generally used LARGE diameter AIR WOUND coils for most transmitting applications.

Many folks don't consider losses in their antenna matching devices. Whatever you do, please look at the overall efficiency of "smaller" or "more friendly form factor" antenna couplers. The losses in inductors of small physical size, particularly toroids, may amaze anyone who calculates them. Typically I don't use anything but air wound coils for these devices, and, unless I'm going on a lengthy backpack trip (which I haven't done for several years), I'll take along my homebrew tuner with 2" OD air wound coils - made in the dark ages of ~1961. Yes, it's heavy, but the measured loss is less than 1 dB in most situations. I've seen >10 dB loss for some tuners of recent design when folks don't pay attention to the laws of physics. 10db loss between a 5 W rig and the antenna means you're getting only ? watt to the feedline or antenna.

The KAT100 was reviewed in QST. Members only article is at
http://www.arrl.org/members-only/prodrev/pdf/pr0501.pdf It is quite
efficient. </members-only/prodrev/pdf/pr0501.pdf> It appears that
Elecraft pays attention to things like toroid losses, etc.

There isn't a review of the Emtech in the ARRL Search. Don't know if
anyone else has done a "hard" review with "hard" loss data.

This type of review seems to be unwelcome in some parts of the QRP
community.

2005. Crank power

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-08 21:41:11 UTC
From: Steven Weber
Topic: 1984 Message: 2005

I've been playing with the LED flashlight with crank charger some more today. I made a couple of mods to it. Added a 5.1V zener across the power jack to keep the voltage from going above that and a couple of .47 F super caps to help keep the voltage steady. Not sure if either of those mods are really needed, but can't hurt, hi.

I can charge my PDA battery, but it sure takes a long time to move it a few percent. Am limited by the charge rate built into the PDA, which isn't fast. I think it discharges at about the same rate that it charges. So, if you use it for an hour, its going to take an hour of cranking to get it back to where it was. Thats a lot of cranking. I think my Zen stone MP3 player has an even slower charge rate. Gonna have to do some timed discharge/charge tests to see if this is going to be a viable option or not.

I don't think it will be a good solution, myself. I believe most relatively modern PDAs use 300-400 mA of current. Assume that's at 4 volts (nominal single cell LiPo battery- ok, 3-7 to 4.2 volts, call it 4.0). That's 1.2- 1.6 watts of power consumption.

I believe you said the generator puts out about 200 mA @5 volts, when cranked at a reasonable, steady rate. Thats making power at a 1 watt rate. Take some off for charging inefficiencies, and I think you'll find that you need to crank 1.5 to 2 hours (or more) for each hour of PDA use. Plus, the cheap gears and such that they use in these things are not meant for that kind of continuous duty.

In short, it would comsume less (human) power to carry the small solar panel(s) and/or additional batteries...

> I believe most relatively modern PDAs use 300-400 mA of current.

It really depends on the usage. If you have a display, that is somehow readable without backlight, you spare about 100 to 200mA current. CPU current depends on the idle times. Generally, PDA with backlight off and no CPU load takes less than 100mA.

> Plus, the cheap gears and such that they use in these things
> are not meant for that kind of continuous duty.

I agree with that. I expect the gears to be worn out after one hour.

I still plan to do some power optimization of PocketDigi software. For example, currently the waterfall is calculated for the whole spectrum, even though only a small window is shown. Calculating just the displayed part will decrease current.

I have not the slightest idea what the losses are in my SLT tuner however with a half wave end fed antenna and 5 watts I had great success on field day and made many contacts, most on CW but some on SSB. As for whether it works on 80 m I did not try it as a half wave for 80 was simply too long for me to deal with as a portable set-up so I avoided the band for the most part.

Well actually I can't remember that far back but I don't recall operating any on 80 m. hi hi

2013. Tuner with a 3b

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-09 01:39:03 UTC
From: cadmanj43
Topic: 2013 Message: 2013

I just finished my 3b today.
It is awesome!
My question is how can I use my T1 tuner?
When I start to tune I get the reset from the over
current protection.
I've already tried lower voltage. (6v)

I bought the kit so I could take it backpacking.
I don't want to take additional equipment.

Thanks for any help.

i'm going to be in the same boat after i finish my ats3b.

i'm planning to use a 50ohm pad built just for this purpose. it will knock the output down by 3db so the tuner will only see 2.5w but keep the impedence seen by the ats3b in check.

if 3db isn't sufficient to keep the ats3b from tripping i'll add in another 3db which should certainly do it. i think my t1 should do fine with 1.25w input.

Others will offer suggestions as to which method to use to put the kit together. I used the solder by hand with the doofus to hold down parts. You can read about it here

<http://www.al7fs.us/AL7FS5ATSprint2.html>

See my photos here

<http://www.flickr.com/photos/shadle/sets/72157602215143718/>

I suggest that you start your SMT experience by trying out a NorCal dummy load. It's a nice tool to have around the shack and it is a good (and cheap) introduction to SMT soldering whether you use the solder paste method or the regular/doofus method.

Pick one up here

<http://www.norcalqrp.org/ncdummyload.htm>

Good luck, and have fun! I did!

I'm afraid your right Mike. The only problem with the solar scheme is I might not be able to spend enough time in the sun to make that viable either. I need to find a really tiny and light AC charger or make one. But when you get to a hostel and theres 10 hikers there who want to charge their cell phone in the one electrical outlet available, thats a problem too. Well, I got all winter to think of a solution.

--- In AT_Sprint@yahoogroups.com, "cadmanj43" <cadmanj43@...> wrote:

Harold,

The T1 is kind of a disaster waiting to happen, because it subjects your rig to short bursts of high SWR/mismatch/reactance as it hunts for the right match. Even though the mismatch doesn't last long, it's intense enough to cause the ATS-3B to trip; and it surely subjects you final amp to some extra stress it doesn't need. The T1 would be a better product if it contained a resistive pad or attenuator.

I own a T1, but I rarely use it. I like my BLT's instead.

I like the idea of using a resistive pad (power attenuator) between the ATS-3B and the T1. The T1 will tune with a watt or so, so a 3 db attenuator would be OK as long as the ATS rig is putting out 2 or 3 watts. However, a 3 db attenuator doesn't look like 50 ohms to your rig unless it also sees 50 ohms. There will still be considerable reflected power seen by your rig.

My tests indicate that the current limit on the ATS-3B is really close to the trip point when running above 10 volts. I ran my rig into a BLT, which looks somewhat like a pad in the "Tune" position. Even in "tune" position the ATS-3B will trip out sometimes.
In "Tune" you're driving a bridge circuit that looks like 50 ohms resistive when it's balanced. When it's not balanced, the reflected power is limited, but it's NOT 50 ohms. Mismatched or reactive loads will still reflect power, they're just swamped by resisance, until you get them matched. So the ATS-3B may still trip. Running at low voltage will help things a lot, because it reduces the PA current. The BLT only needs a watt or so to light the LED in the balance detector. I think most of us can find an acceptable compromise.

A radical answer is to use a Norcal "Tuner-Upper" to tune the tuner/ antenna - these devices are an independent source and bridge with an LED indicator. They fit in an Altoids box - yes, they're as large as the AST-3B - and they work real well. You have to have one for each band. Just tune the tuner for a match with the Tuner Upper, attach the ATS-3B, and operate.

Of course, you could raise the current limit in the ATS-3B - I raised mine a little - but there are risks in this. It wouldn't be hard to raise it a bit for tuning, and then switch it back for operating. That's an inconvenient mod, and it doesn't solve everything, since the time you're most likely to blow something is when you're tuning.

You're not going to take this rig "stock", connect it to a 12V battery, just run it into whatever tuner you like, and load up your bedsprings or gutters without thinking about the problem.

A better strategy is to come up with known good antennas and tuners that agree with this rig, maybe limit the voltage for tuning, use a bridge or attenuator, and then be happy that your rig is running into a good 50 ohm match and is operating happily. The final in this rig is very efficient over a wide supply voltage range, and it uses a minimum of battery power, but it requires a correct load. The current limit provides some protection, but only for mismatches that cause the PA current to rise.

Don't forget the old trick of first adjusting your tuner with your receiver. When you've peaked the band noise as well as you can, switch to "Tune", and then your rig will already be close to a match.

Sorry to write another essay, but this subject is very much on my mind, because I intend to use this rig for portable/hiking and with antennas that require a tuner.

Good luck

i think a resistive 6db pad formed by two 150ohm resistors to ground
with a 36ohm series resistor between them, would present:

150||186 = 83 ohms when open

150||36 = 29 ohms when shorted

so less than 2:1 at either extreme.

similarly a 3db resistive pad with 295 and 18 would present 3:1 max.

what's the swr limit for a ats3b when run at 12v?

--- In AT_Sprint@yahoogroups.com, "John" <af4ex.radio@...> wrote:

In my opinion the BLT is a nice compromise tuner for portable work. I have 5 of them now, none is stock, and each one is optimized for a range of frequencies. One covers 160 through 20M, another 5 through 30 Mhz, one is just for the HF bands, one is a true Z-match for 1.8-30 Mhz, and another is just for 20-80 Mhz. The "stock" BLT has a very limited frequency range. Getting more than a 4:1 frequency range while matching a wide range of reactive loads requires adding switches for extra capacitance, using high capacitance polyvaricons, at least one switch for high frequency taps on the main toroid, or more radical mods.

Even though my Z-match version covers a huge frequency range, and works well over much of that range, it suffers from unbalance at the high end, and its efficiency is not as good as the regular BLT. A true Z-match uses a tapped coil with a double-tuned circuit, and ideally the two ranges overlap. There's lots of info on Z matches on the internet. Charlie Lofgren's original article is worth reading.

The stock BLT is a good starting point. It's inexpensive, works, and you can modify it. Get familiar with it, and then it's pretty intuitive to increase or decrease the turns on the toroid, add switches for taps, extra caps, use part of a ganged polyvaricon cap for the high-frequency end, etc.

People have asserted that the BLT's are inefficient - but I have run two of them back-to-back, one feeding the other with balanced line, and then back to a 50-ohm load and meter, while adjusting them both for more and more reactance - and I think you'll have a hard time beating them, at least for QRP and balanced lines. Anything better will be much larger and heavier, and that's too large for lightweight portable work. Of course there's more loss as you force them to deal with more and more reactive power.

The Q of the main inductor is well over 200, especially if you use a T106-6 (yellow) core instead of the stock T106-2 (red) core. With any reasonable antenna and feedline, a BLT will deliver good efficiency and convenience. If you want to operate on several bands with just one antenna, you'll find a way to get there.

One option is to carry two modified BLT's for those few times when you really need to work from 80 through 15 meters.

If you want to use an unbalanced tuner, the addition of a good current balun may enable you to use balanced line. I tried this with my T1, and my KX1, and it seems to work OK. I have no idea how the

efficiency holds up with reactive, mismatched loads...but many folks
use this approach for QRP, as well as QRO. But a tuner and a balun
weigh as much as a BLT.

This is a big subject, there are no easy answers, it gets down to
complex numbers, Smith charts, and multiple tradeoffs...

I think it's a lot of fun to work through this stuff though. We can
learn a lot from playing with tuners and antennas. I'm sure not
sorry for the 5 BLT's.

If someone invents that "ideal tuner", they could sell them for more
than the ATS-3B's cost.

Consider that the genius engineers that created the Yeasu FT-817,
which does many things well, didn't even offer a tuner to go with it -
????? Is everything 50 ohms in Japan? I don't think so...

Jim,

Thanks for the numbers. My 2 cents worth here is that metal oxide resistors (MO) work well for these jobs.

I think we're going to need 6db, unless we modify the rig's current limit. Mine is already near the "stock" trip point, into 50 ohms, on 15 meters, with 12V. Once I raised the limit to 0.9A I was able to actually tune the rig into a BLT.

It's not just the SWR, it depends on the magnitude and phase of reverse power the rig sees. Some mismatches reduce the current draw. Complex impedance. I think the rig may trip at less than 2:1 SWR, even if it's modified, on the upper frequencies when running on 12V. The current varies a good bit as you change the load.

I hope others who have got to this point will add to the discussion. We could take Steve's advice, run on 9V, and keep life simple. That rig runs almost perfect on 9V.

I just finished my 3b today.
It is awesome!
My question is how can I use my T1 tuner?
When I start to tune I get the reset from the over
current protection.
I've already tried lower voltage. (6v)

I bought the kit so I could take it backpacking.
I don't want to take additional equipment.

Thanks for any help.

Harold,
N8RQJ

Has anyone thought of placing a bridge type SWR indicator in line, (just for
tuning),
Doesn't this limit the SWR seen by the radio to 1.5:1? I wonder if this
would work
with the T1 tuner.

Good morning,

I had the same idea yesterday when I was thinking about how to protect the finals on tune-up. I was planning on a 5dB pad, but 6dB will work and give an extra dB of protection. I was planning on mounting three resistors between two BNC plugs (one male one female) and then encasing the resistors in epoxy. The whole assembly would be about 1in - 1.5 in in length and a little wider than a BNC connector. Great size for backpacking.

Buddy,

The 3B has the same PA but has a fast current limit circuit in the B+
line feeding it. Under some conditions of mismatch, as when tuning a
tuner, it may trip. The "stock" limit is set at 820 mA. The effect
occurs more easily if the filters are adjusted for maximum output.

I think using a T1 without a pad is rough.

>do those shoes that light up work? I'm not
>joking...visualize...electric boots...

The shoes that light up run on a battery. I have one taken out of a sneaker, one of the early ones. A small battery, LED and reed switch with a floating magnet are incased in a block of clear plastic. I have heard of experiments of putting piezo electric thingies in the heels of shoes, but they don't produce much energy.

I was thinking of addapating the method used in the shake and charge flashlights to hiking poles. Put a spring and strong magnet inside the pole and wrap a lot of wire around the outside. Running wires back to the battery might be a problem though.

Maybe a thermo pile you put in the camp fire at night?

>design?

I know several people have blow up the PA (and keying transistor) in the 3/3A when trying to use the T1 and 12 V rig supply. So it is a problem.

What has changed in the 3B is the addition of the over current protection. Now that we know how easy it is to draw over 820 ma with a miss matched load, its amazing there hasn't been more trouble with blown finals in the earlier rigs.

Does the T1 remeber settings? If so, maybe it can be pretuned with a more robust rig.

I built something I've been meaning to kit up sometime. Its like a Tenna Dipper, but uses a programmable R/C oscillator chip from Linear tech. It will generate preset frequencies in all the ham bands, 80 to 10 meters. It is primarly intedend to be use for tuning loaded short verticals, like the MP1 or PAC. It can be placed near the antenna, so you can adjust the coil for a match with out having to run back and forth to the rig and watch a SWR meter. That can be time consuming. Of course, it can also be used to preset any antenna tuner (except an auto tuner). The board fits into an Altiods tin along with a 9V battery.

I see that now, so I will sheepishly return the the cave where
I had been lurking.

Interesting paradox though, a trail radio that isn't trail
antenna friendly. Seems for the price you pay in terms of
bulk, weight and cost of a tuner you could trade that for
a more robust PA.

the t1 has a serial port that can be used to initiate a tune or recall a band. according to the manual it has one memory per band from 160-6m with the proviso that 60m and 40m share a common memory.

the smallest of micros would likely be sufficient to do the signalling and could be powered for a year or more on a 2032. elecraft makes a cable that works with an ft817 that has such a microcontroller in it. perhaps that could act as a model for a suitable design.

Hello All

My favourite ATU for QRP operation is the T1 ATU from Elecraft : see :
http://www.elecraft.com/ ; much better than the BLT, but difficult to
compare a very sophisticated ATU with a a manual tuner ...

It is rather expensive (135 USD), but really, it can match nearly
everything between 80 to 4 m bands, in association with a 1/1 balun
if needeed !

Thanks for all the info.
I started the snowball effect! LOL
I've used the recieve method succesfully but it takes some time.
I do it in test mode on the T1.
It is intended for L/C & Relay checks but works as manual tuning.

I think I'll try the Pad method first.
It seems really simple.

I'll try for my first contact with it tonight or Saturday.
That's if I can slow someone down to 5-8WPM. Hi Hi
I'll post pics after I get my label on it.

Thanks Steve, for a great little rig!

Thanks all!

Harold

Not really Mark. No matter how robust a rigs PA is, depending on the type of antenna and feed line you use, your going to need some kind of tuner. If you use a resonate dipole, you don't need any tuner.

My favorate trail antenna is the end feed half wave, as it is the simplest and quickest to set up and works pretty good. A single band tuner for one of these can be made quite small and light.

The only issue is with the T1 tuner, which IMOHO adds too much bulk, weight and expense for the little bit of convenience it might give. A manually operated version built in a manor similer to my ALT tuner can be made for a fraction of the cost of the T1.

BUT !!!! Steve said that if he makes a third batch, and that possibility exists, that it wouldn't be until after the first of the year. It might help provide encouragement if folks would let Steve know privately that they are interested in getting an ATS-3B. It has to be worth his while to do another batch.

One of the best reasons to use a tuner is so you can use one antenna on several bands. A dipole or loop work well over a wide range of frequencies if fed with low-loss line and a tuner.

I want to try Steve's end-fed half wave. Eznec says it works reasonably well. You don't need to carry a bulky feedline with this antenna, and with one high point, it'll go up easier and faster than most other efficient antennas.

You'll make more QSO's if you're on the rig, rather than trying to get another line up in a tree.

The Elecraft KX1's final is fairly robust - but it can generate parasitic oscillations with a 2:1 SWR. You need the KAT ATU, or an external tuner, to safely use that rig. I know, because I have one. That's being sold as a "trail friendly radio". The internal tuner will match only certain kinds of loads. It's still a fun radio, but I like the ATS rigs better.

2046. Re: Tuner for 80m-15m?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-10 01:26:47 UTC
From: tf3kx
Topic: 1995 Message: 2046

If Steve makes offers another batch of the 3B I just may sign up for one (I don't have any of his kits yet).

In that case, I would probably go for a simple inv-L network, that can be fed from either side. The main reason is that it uses only two variable components (L and C), which leaves no redundancy when we match an unknown impedance (R and X) to 50 Ohms. Thus, this kind of tuner uses a "minimum amount" of circuitry for matching, making me believe that its losses would be kept relatively low. This is in contrast to some other tuner designs, where the controls are 3 (or more), where the additional control degree of freedom may affect the Q of the circuit and leave us with perfect matching to R and X, but at a Q that results in more losses than necessary.

Hello Denis

I use the T1 with my ATS3A and ATS3B for many months
It works perfectly with my 2X20m doublet + 450 ohms ladder line on
all bands from 80 up to 15m

The only thing to care is the overcurrent sensing system on the
ATS3B : during matching process, the T1 goes through high SWR areas,
and the overcurrent system trips : I found that installing a 10 ohms
resistance in serie with the power supply works well : during RX,
there is no noticeable voltage drop, and on TX, the supply drops to
8.5 volts (with 12v in the entry) : so the current is always low
enough to make the matching process possible until a good match, and
is safer for the 3X2N7000 !!

2055. ATS3 and Tuners

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-10 22:36:46 UTC
From: ve3wmb
Topic: 2055 Message: 2055

I have been reading the recent discussion about the issues with using the T1 and ATS-3B.

I did some playing today with my ALT Tuner(another KD1JV design). A while back I bought the commercial version from Hendricks QRP, which has now been replaced by the SLT (uses switches rather than two pin headers to select the different toroidal inductors).

What I found was with the recommended 51ft wire and a 32foot counterpoise wire on the ground I am able to get a 1:1 match on 80m/40m/20m with no problems. I already knew that 30m is a bit problematic (~2:1 SWR) with this wire length but I have found that coiling up a couple of feet of wire will allow it to match on this band. This tuner uses a resistive SWR bridge so that in "Tune" mode most of the power goes into a 50 ohm dummy load keepin the ATS3A PA very happy. As this tuner fits in an Altoids tin it makes a great companion to my ATS3A and it will be what I use on the trail from now on.

Michael VE3WMB

P.S. I suspect that the SLT is slightly bigger than the original ALT but has the advantage of making the inductance selection a bit simpler.

The device has has nice format for digital modes: big display, big keyboard. It is no more produced, but you could get it on e-bay for a reasonable price.

It does not have an audio in jack. You must do it yourself. If you are not brave enough to do it, either use audio coupling (put ear bud on the microphone hole, works quite well in quiet environment), or buy something else.

Hi Jonatan.

> Do you have any tips or instructions on making this mod?

I modded my iPaq 3630. First I added a SMD 2.5mm jack socket, that I removed from a broken cell phone. It happened, that RF induced into ground loop created by phone and mic cables connected to ATS3 on one side and PDA on the other side burned grounds and audio PA in the PDA. After this incident I bridged audio PA and PDA was no more able to drive earphones. Then I removed the added 2.5mm socket, disconnected path of the earphones ring contact and connected the microphone there. The earphone socket has a disconnect switch in my case, which I reused to disconnect internal microphone. So now I could connect PDA to ATS3 with a single cable and there will be no dangerous ground loops closed through the delicate PDA board.

I found out one needs to attenuate audio signal of ATS3 quite a lot before you feed it into microphone input of the PDA. I put 1/50 voltage divider in the audio cable on the PDA side. If the attenuator is put on the ATS3 side, PDA will pick up a lot of noise. I plan to build the voltage divider into the PDA later making it more a Line In than Mic input. The microphone is powered, do not forget to decouple it by a capacitor before connecting the attenuating resistor divider.

73, Vojtech OK1IAK

hi
likewise i don't see an audio in or mic jack but here
is a mic. if there is an alternative to putting the
headphone next to the mic i would very much like to
know about it.
thanks

Perhaps a bluetooth project?

Well if you plugged in a bluetooth devices to the Jornada then came up
with blue tooth addapter for audio on the AT_Sprint side.

Here's a short forum section on the 720 bluetooth posibilities:
http://www.hpcfactor.com/forums/forums/thread-view.asp?tid=5219&start=1

>yourself. If you are not brave
>enough to do it

so has anyone tried this with, specifically, a jornada
720?

i.e., to do digital with and ATS radio

(i am not totally lacking in bravery but if someone
else has already figured out how to do this right then
i would sure like to know how to do it, too, and its
clear that others would also.)

thanks

Topic: 2057 Message: 2070

Bluetooth.... This device is pre-bluetooth by a couple years.
I am pretty excited, though. Right there at my desk at school I got the Pocket Digi installed on WinCE on my Jornada 720, and with an earbud held up to the mic hole (far from ideal--but surprisingly effective) and replaying the VERY helpful K7AGE YouTube PSK31 test video, I was readin' PSK31 on my palmtop device! I'm not too cool for school--I was really excited it was working! I could imagine a crude sort of rubber boot that would shut out some outside sound (like the olde modems I used to use in 79 in junior high!)--but drawing from some live taping experience I had in my OTHER obsessive hobby, there's a way to make a little attenuator that would bring the Bee's output down to mic level if I were to hack in to the Jornada 720. This was the bravery Vojtech was referring to.
Is there anybody who could shoot me over a bit more detail on how I would brew up such an attenuator? (In slightly more detailed terms.)
Anyway, things are going well on the road to PSK31 with the ATS3B.
Jonathan

Hi Jonathan.

There is a known bug in PocketDigi 1.0.10 build for Jornada. The menu is missing.
Please use version 1.0.9 until I provide a bugfix. I think there is no ATS support in
1.0.9, so you would not be able to TX though.

2073. Potentual problem with 15M transmit in 3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-12 21:48:55 UTC
From: Steven Weber
Topic: 1999 Message: 2073

Carey, KX0R, discoverd a potentual problem when transmitting on 15 meters. He discovered that after a few minutes of transmitting, the output spectrum went all to hell. This is only a problem on 15 meters.

I tried to duplicate the problem with my rig and after a solid 5 minutes of key down with 5 watts out, I failed to duplicate it. Then I put the heat gun to the board and it became apparent.

What is happening is this. The roll off of the DDS output filter is somewhat less than 21 MHz. If the ferrite chip inductors in the filter get warm, thier value goes up. This can reduce the output of the filter to the point the comparitor in the DDS doesn't have enough singal to work with and becomes erratic.

The extent of this problem is hard to judge. It depends on the exact value of the inductors you happen to have and the operating tempature. If your values are on the high side and your operating outside on a hot summer day, there is likely to be a problem.

One way to tell is to transmit into a dummy load and monitor the output power. Heat the DDS filter area with a heat gun and see how hot you have to get it before the output drops off significantly. If you have to get it real hot, then your okay. If it only takes a little heat, then you need to do a fix.

Thankfully, the fix is pretty simple. We just have to rise the output level of the DDS a little. This is done by reducing the value of R15, the 3.9K resistor. Droping it down to 3.3K should do the trick in most cases. 2.7K would give some more margin. I don't have either of these values on hand, but will get some in case anyone needs them.

Hi Steve.

I think I ruined my LiPo pack after I fell asleep with the rig powered and did not disconnect it for the next day. LiPols are very sensitive in this regard. They inflate and lose capacity.

How about to use a 5V stabilizer with enable pin and switch the whole analog part off after some period of inactivity? It would also be very useful to switch the rig off after the battery falls under a defined threshold.

How bout a 10K resister in parallel with the 3.9K
(giving about 2.8 or 2.9K). I know it's a little tight
but 103's are pretty common on circuit boards.
Everyone has a stash of old circuit boards to scavenge
from right? :)

Great idea Mike.

Stacking them sounds like a very elegant fix. Especially if R15 and the parts around it are already soldered in. How easy is that to do?

I love this radio stuff!

Sorry to hear that.

>How about to use a 5V stabilizer with enable pin and switch the whole
analog part off after some period of inactivity? It would also be very
useful to switch the rig off after the battery falls under a defined
threshold.

The analog section doesn't really use much current. Its the DDS clock and
the DDS chip which consume the bulk of the rigs current.

I tried making a version of the rig which had an electronic on/off switch
to turn everything off but the processor. Main reason for this was so I
could implement a real time clock. It got a lot more complicated than you
would think at first. I never did get it to work right. But now that I
think about it again, maybe now I could with a different approch.

A simple auto low voltage disconnect circuit wouldn't be too hard to make.
It would only need a P channel power fet, a 2n7002 and a voltage reset
superviser chip.

Vojtech,

If we use a protective PCB with a lithium pack, we are protected from overcharging, overdischarging, and overcurrent. These very small, low cost PCB's are available from suppliers who sell the cells and packs. I got some from batteryspace.com . It is dangerous to use lithium cells without these protective circuits - lithium ion cells are particularly dangerous if unprotected.

Steve,

Thanks for posting this so fast! Wow, I nearly fell out of my chair when I read this, I was so happy! I thought I was going to have to replace that DDS chip...

It's so nice when someone tells you your crisis is not your fault, and there's an easy way out! I really appreciate your clear explanation - it agrees with everything I observed, and it explains why the heat works so fast!

I tried 15K across R15, and the problem was greatly reduced. I had to get things hot with the embossing tool before the noise showed up this time.

I have two big questions still:

1) If the problem is mostly caused by the chip inductors drifting, what do you think about replacing them with small toroids? I have some of the smaller micrometals cores, and I can hit 1.5 uH with a core that will fit in the same space as those chip inductors. I even have some of the yellow type 6 material, which is very stable. Toroids might have a higher Q than chip inductors, so the filter might behave differently, especially since it's "on the edge" at 21 Mhz. It might even work better.

Is this a good idea? Should I try for 1.5 uH, or a little less? What happens if the inductors are too small and the filter's knee moves up in frequency? The nice thing about toroids is that we can adjust them a little.

2) What happens if R15 is too low? What are we trading off as we lower R15? Can the DDS be damaged, or does some new problem appear?

Thanks for your help with this tricky bug!

> packs.

I am using 2 cell 1.7Ah pack, that was designed for powering air plane model and I also use it for that purpose. The cells are never equipped by the usual the switch off circuit in the model, but usually the propeller regulator takes care of it. But you are right that it is wise to use it with the radio.

As the author of the article in question, I DO NOT recommend this type of ciruit to control the ATS rigs. The reason is due to the slow transition through the conduction point of the FET at the end of the discharge cycle. This leads to the load seeing a slowly dropping supply voltage, rather than a quick shut-off. This situation can lead to corruption of the EEPROM contents of some microcontrollers, in some cases. It is for this reason that I only recommend this cirucit for control of relatively simple, analog devices.

For LiPo pack protection, I also recommend the protection PC boards that have already been mentioned. They are very inexpensive, and protect the LiPo pack by disconnecting it from the load (or charger) if any single cell goes below 3.2 volts, or goes above 4.2 volts. I use them on all my LiPo packs.

Hi Steve.

> The analog section doesn't really use much current. Its the DDS clock and
> the DDS chip which consume the bulk of the rigs current.

You are right, I forgot that.

I think if you suspend
- 5V regulator (a part with suspend pin will be needed)
- DDS oscillator (part with suspend pin will be needed)
- DDS (programmable)
- CPU (programmable)

the overall current will be next to nothing, probably around 0.5mA, which is 12mAh per day, 84mA per week. Probably not good enough for real time clock, but certainly good enough to save the battery. I think the current will consist mostly of quiescent current of the 3.3V stabilizer and current through the pullups.

> A simple auto low voltage disconnect circuit wouldn't be too hard to make.
> It would only need a P channel power fet, a 2n7002 and a voltage reset
> superviser chip.

I would prefer to control the low voltage by the CPU to be able to select battery type.

Those circuits are certainly useful, but they will not save you power if you fall asleep and find a flat battery in the morning. No radio fun during the rest of the trip.

From: John A. Evans - N0HJ
Topic: 2074 Message: 2089

Greetings all,

I suspect that Steve/KD1JV and Mike/W1MT could answer this one pretty fast, plus I suspect the answer is yes. I do want to run this by the experts before I start playing around.

If the DDS chip was replaced with a 75 MHz version, and the clock oscillator also replaced with a 75 MHz clock, would it be possible to put the ATS-3B on 12m, given the right module components and software changes? Are the modules simple double-sided boards? It sure would be nice to have yet another higher band for field work.

Topic: 1999 Message: 2092

>1) If the problem is mostly caused by the chip inductors drifting,
>what do you think about replacing them with small toroids? I have
>
I would not recommend doing that. Toriods are not as "self shielding" as
many people think. Due to the fairly close proximity to the PA output
filter, there is a real possibility that the transmit signal will get into
the DDS filter. It will also likely be out of phase with the signal from
the DDS chip, possibly causing some strange oscillation problems.

>2) What happens if R15 is too low? What are we trading off as we
>lower R15? Can the DDS be damaged, or does some new problem appear?
>
I'm not sure what happens if R15 is too low. Making R15 smaller in
resistance makes the output amplitude go up, so there is some increase in
overall current comsumption.

75 MHz clocks don't seem to be commonly available. I tired a 80 MHz clock with a 9834 I had from before AD changed the clock speed spec for the chip and it worked fine. With the 80 MHz clock, I was able to make the rig work on both 12 and 10 meters.

However, there were two issues. One, the rig's current went up to over 50 ma on receive due to the high current of the 80 MHz clock and fast clocking of the DDS chip. Second, the transmitter output filters were very touchy to adjust. Very small changes in the spacing of the wire on the cores made a huge change in output power.

Even though it was possible to make the rig work on 12 and 10, I decided it wasn't worth the current penalty and the expense of yet another two filter boards, especially since it will still be some years before these bands are of much use.

It made more sense to only go up to 15 meters, which only added 10 ma to the current compaired to the 3A and these bands had more chance of seeing use in the near future.

Anyway, I'm working on a small SSB rig which will cover 20 to 10 meters, though at the moment, I'm in no rush to get it done. Just want to have it ready for when these bands start to become active again :-)

Easy to do in the firmware. In addition, to the
increased current consumption and low pass filter
touchiness mentioned by Steve, you may also have to
look at:

1. The elliptical filter out of the DDS.

2. The switch that controls the PA (74AC*** vice
74HC***)

Not sure if both of these would have to change or not.
Haven't done the analysis properly...

While we're thinking about additional bands, what would it take to get on 160 meters, or 60 meters (assuming the FCC grants the petition to open it to CW & narrow digital modes)?
No issues with the DDS for these modes, I assume. It might be nice for the firmware to enforce the channelization on 60m. Does the choke on the PA collectors have enough inductance for 160m? How much room is there in the range of voltages used for identifying band modules?
The 160m filters would probably use T-1 (blue) toroids.

I ONLY recommend a charger designed specifically for LiPo batteries.
You can find them at all the places that sell LiPo cells and packs.
You must use a charger that is set for the specific number of cells
in the pack.

For my cells/PC boards/ chargers, I have had good service from

www.all-battery.com

They have a charger on sale right now for $23.00:

http://www.all-battery.com/index.asp?PageAction=VIEWPROD&ProdID=478

I use this one, and it works well.

There is no technical problem for 160. Making the filter board is a physcial challenge. I get my cores from Diz, and he only carries the T50-1 size. Which is what you'll need anyway to fit enough turns on the core.

I also see no real point in doing 160. After all this is suppost to be a backpacking rig! Even 80 is marginal for that. 160 would be just crazy!

--- In AT_Sprint@yahoogroups.com, Dale Putnam <daleputnam@...> wrote:
Dale,

Every year I operate FD in WY, and I enjoy it as much as anything. I have actually tried operating 80 CW for FD, and it is unusual to get more than a few contacts, if I even hear anyone through the QRN. Most of the ones I hear are QRO, and few of them can hear a QRP station. 80 is so bad for FD that I've never even listened to 160 during FD.

I don't live far from you, and I know that a lot of things are better up in the open spaces of Wyoming than down here in semi-urban Colorado - but I think you have just as much summer QRN as we do, and I'm so unimpressed by 160 in the summer that I would never even consider trying it from a trailside spot or campsite. I think Steve has stretched reality pretty far to include 80M in the ATS series. It's there because some of us use these rigs for sprints and events like Run for the Bacon, where 80M will actually yield some QSO's during quiet nights in the colder months.

I'd be interested to see how many people reading this thread in this group have actually made an 80 meter QSO portable and QRP, with any radio. I have done this, and I think it's rough. 160??

Of course, it would be possible to work one of the 160M CW contests in the winter, camping somewhere, with QRP - the thought has occurred, because a large antenna could be put up at special places outdoors. On the other hand, I've actually operated QRP while winter camping in the snow, in a tent, at temperatures near zero, and I don't like much more than a couple of hours of it. 160? I know you guys are tough in Wyoming - and your winters are really rough. How would you keep an antenna up in all that wind?

I think it would easier to pack a larger rig on that horse than to wind the toroids required to put an ATS rig on 160.

This message caught my eye a few weeks ago, and I ran out and got me a Jornada 720. It looks nice, gets remarks, runs 1.0.9 PocketDigi--but currently cannot transmit PSK31, as far as I know. Stand by for possible bugfixes, but unless I am mistaken this unit is NOT compatible with the ATS3B for PSK31 at this time.
Just making that clear, because the message above sorta led me to believe the opposite was the case.
Oops!

From: Tim Keene
Topic: 2106 Message: 2108

I think Steve made a logical and sound decision not putting 160m in the ATS-3B. Playing the devil's advocate for a moment, Some folks like to use their QRP rig occasionally at home as the main rig and work QRP exclusively for a while as I do myself. For some maybe it's their only rig because they live in a apartment complex and are worried about TVI or whatever. In that case, having the extra bands including 160m would be pretty cool. I probably would not use it myself but the option would be nice.
Just food for thought and my 2 cents worth.
Tim - K5DEZ

Hi Carey,
yep, it is fun, and sometimes it is rather interesting when the wind blows the antenna down into or around the horses. They have all learned what happens to them with wire... electric fences and all. So... with antennas they get rather unhappy... so.. one of two choices... either tie antenna down or take it down.
So.. I have tied it to the saddle on the trailer... or to the saddle horn, as it is setting up under a tree.
And the noise isn't so bad, I use rx antennas for summer too. That always helps, and as far as fd goes, I usually get covered with signals on everything down to 160, then after 10 pm, that picks up pretty well too.
No, the rate doesn't stay nearly as high as when I get talked into either 100 or 1kw. But, it isn't as much fun for me either. Yes, I could take a bigger rig, but i kinda like to eat too. and have room for other stuff too.
Last trip out was up to about 8500 in the Green River Lakes area, then on up to spike camp at 10+, in a tent, temp was chilly, something past froze the water bucket... but it was quiet, and nice on 80, with a dipole into trees. I've used a vertical too, in the same trees.... but that doesn't work dx very good... mountain rock don't make for good ground field. And I don't really want to spread out 30 or 40 radials to make it work nice either.
So.. 160 in the summer would work, high, quiet... well.. with a rx antenna, and try for some ZL or VKs,
oh, what is the rx antenna? Well that is really easy... all the left over wire... or whatever... laid out.... over the rocks and not real high. Preferable away from where the horses are... and take that up at night... the elk don't like trippin over it. They have been known to tangle in it... and it ain't no fun to chase a radio down the elk trail at dark thirty... with only a pair of boots and a hat... thank goodness no one had a flash or camera...

Mike,

If you use 2 lithium cells you'll start out just over 8 volts and drop to something above 6V. With 3 cells you start just above 12Vv and drop to something above 9. Please look at your battery's data sheet to determine the maximum charge voltage and the minimum discharge voltage. Going above the maximum charge voltage may be dangerous, may shorten battery life, and should trip the protective circuit. Going too low will damage the battery and should trip the protective circuit. Don't cheat - use a protective circuit with lithium cells!

The ATS-3 radios run nicely anywhere from about 5.5V to 12V. Running at the high end requires more attention to providing a correct match. Read through previous posts for more information - there's plenty.

Good luck

Dale,

Thanks for your message - it popped up twice, and I enjoyed reading it twice! I hadn't thought about horses and wire, or elk at night, but I believe you. When I did FD in WY, I shared National Forest land with some cows - I got a little nervous when some of them came through - I had a long run of ladder line strung through the low branches of some pine trees - they left it alone though.

Maybe I should try a receiving antenna next year...

2118. 15M DDS Filter Heating Problem

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-14 05:24:22 UTC
From: radio_kx0r
Topic: 2118 Message: 2118

I finished Steve's suggested change to help the DDS work correctly on 15M if the components get hot. I took the suggestion made here and added a 10K (103) resistor right on top of R15 3.9K (392). This parallel pair yields 2.8K. I tested the rig with some hot air, and the problem I was seeing is no longer apparent, even with everything hotter than I expect to have it.

Adding the 10K resistor is the easiest thing you can do to lower R15.

My rig's current consumption on receive with no signal is now just over 37 mA. I think it was about 35 mA before the change in R15. I added another 10K in parallel just for a test (this gives 2.2K for R15), and the current increased about 2 mA, from about 37 mA to about 39 mA. On 15M these currents are almost 1 mA higher.

So 10K across R15 is the fix for me.

If you never plan to use 15M, and your priority is maximum battery life, you may choose not to change R15.

I tested all the bands at different power levels and everything's nice now. I'm ready to box it up and get on the air some more!

Thanks again Steve!

I've gotten my ATS-3B mounted and am tuning in the last of the filter modules and testing the performance of the rig. I noticed that with 12V drive th PA overcurrent protector will flip, but if I put 10ohms in series with the ATS to drop some voltage it operates fine.

Has anyone else had this issue? 40 / 30 / 20m operate on 12V just fine.

Gary

OK,

But buyer beware at all battery. I ordered some
transmitter packs albeit they were NiMh packs and
absolutely none of them came close to their
2000mah rating. I gently cycled them and then did
some
C/10 charge cycles and C/5 cycles and could was lucky
to get them to 1300 to 1500mah.
Granted they were cheap and run the R/C transmitters
longer than stock packs but are nowhere near their
alleged rating.
Oh BTW, I bought six packs and not a single one
performed as rated so I don't believe it is a fluke.
They were of the "Tenergy" brand.
YMMV with the lithium cells.

Gosh,

That's my only intention once I get it done.
Just have a mini-station with a QBSA to run from
home. If I need more power, will connect up to
an HF packer AMP, add a more powerful antenna tuner
and
one is in business. In my estimation, couple this
to a stealth antenna and it is a perfect combination
for home/base use in an antenna unfriendly atmosphere.
Only thing left to worry about would be TVI. That
would
probably only be an issue running the amp and where
I'm
at, less of an issue because folks are on cable.

If you need to clean the red plastic that's supplied for covering the LED display, don't do what I did and try cleaning it with isopropyl alcohol. The red dye comes off, and the plastic turns foggy. Only one side seems vulnerable, so you can test a corner and decide what to do.

Go to Wal-Mart and get a bottle of the liquid glasses
cleaner in the pharmacy section generally by the eye
solutions. I find this works very well on clear
plastic in radios and very safe.

I do admit though, I had an old pair of prescription
glasses with plastic lenses. I wore them to spray
paint and they got "hazed" by some of the paint in the

air. I figured, "What the heck." I took lacquer
thinner to them and by gosh they cleaned up very
nicely.

I believe though with the cheaper clean windows on
electronic parts, stick with the gentle lens cleaners.

Hi,

I want to make it clear it was with the NiMh packs
with connectors for R/C radios.
The Lithium or Lipro packs might be a different/better
story. They are reliable and sent me my order

promptly. Got some rechargeable 8.4V transistor
batteries from them and they perform as advertised.

Hi Carey,
The only thing with the open wire line, low across the tree limbs... is if the cows, or elk smell the sweaty handprints... they will chew the wire.. looking for salt. Unless, they have access to salt easily somewhere else. I've even had squirres, mice and other associated salt miners chew wire for salt.
I'm pleased that you enjoyed reading. Tis fun to share the Wilderness or Forest with the natives.
And talk to the world at the same time.

Steve,

After doing the firmware upgrade, do we have to do the reference
oscillator and local oscillator calibration again?

Hi Tim

160m for the ATS3B is not a big problem if someone would mod the firmware. I use my moded ATS3 on 160m on regular basis. There is a slight issue with the comparator on that low frequencies limiting the output a bit. But it works fine so far. Cores for the filters are wound on blue amidon T30 cores.
The RX is excellent there as you can hear DX very close to strong stations. With my 2.5W from 9V I worked all around europe with my doublet 12m up used as a Tee - Ant against my heating system.

2134. Re: Simple programmer interface

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-15 20:44:18 UTC
From: Dave
Topic: 1838 Message: 2134

I think it might be more accurate to say it depends. Mike's ATS-3/3A firmware does require recalibration after an update because it uses the programmer to write defaults directly to the nonvolatile data memory. The programming operation will fail if the programming software is not configured to rewrite the defaults, so it must be performed.

On the other hand, Steve's 3A and 3B firmware does not use the programmer to write defaults directly to memory. The executing code examines the memory and only reloads defaults if it appears that the nonvolatile data memory is blank (erased). Whether or not recalibration is required depends on whether or not the programming software is configured to erase the data memory during the firmware update.

I can't say regarding earlier ATS versions, I haven't looked at them.

Maybe not. The earlierversions of IAR C-spy errased the whole chip. Later versions allows you to tell it not to errase the information memory section. I forget off hand if that option menu comes up automatically or if you have to find it.

Also, disregrad any error messages which come up after the firmware has been loaded into the chip.

Thanks for the additional info, Dave. My question was in regards to the ATS-3B. I just wanted to know if I had to hold off packaging the rig until after I get a chance to upgrade the F/W. I want to complete the setup and play aroound before upgrading.

Could you answer another question? I am trying to calibrate the local oscillator by monitoring TP2. It is stated to note when the signal starts to decrease, but going either tine up or tune down the signal amplitude is constant. However, the tone frequency in the headphones does rise and fall a step on the button presses. I also tried looking directly at pin 1 of U3 and saw the same results.

Am I interpreting the procedure correctly? Is the signal amplitude at TP2 supposed to rise and fall?

Topic: 1838 Message: 2137

One more thing about redoing the calibration. If the firmware changes any thing in the flash memory (such as location or whatever) you should load the flash from the programmer and recalibrate. Steve doesn't change the flash stuff often but I have been known to move things around a little. :) I would always opt to recalibrate the rig after reloading the firmware. If you are doing an update of mine or Steve's firmware then you will be ok by remembering the clicks you used on the previous version. Don't try this across the version because I use different steps during calibration. (At least for the 3a they were different).

I am putting the finishing touches on my 3B firmware and hope to get it out in the next month..... We shall see......

As far as calibration, here is what I do:

I use a computer and seperate receiver. Basically, you tweak the cap on the main board to put the filter where you want it (generally centered on 600Hz). Then, you put the TP1 signal on WWV's carrier on the seperate receiver to get oscillator calibrated. Last, I put the tone on the same 600Hz spot that I centered the filter in the first step. This involves connecting the computer to the ATS rig, then the seperate receiver, then back to the ATS rig for each step. I have more detailed instructions on my website (they are for the 3 so ignore references to the transformer).

Doing it this way makes my sidetone to match the annunciation tone and it makes zerobeating a snap.

2138. Interesting 3B Band Module Problem

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-16 04:17:16 UTC
From: Jim Fraser
Topic: 2138 Message: 2138

My 30M module is recognized by my ATS-3B as a 40m module and my 40M module is seen as an 80m module. I verified that I have the correct resistors on these modules. With the module removed I measured the resistance between pins 3 and 5 and the got 9.79K for the 30m module and 21.6K for the 40 meter module, looks OK. The other modules were properly recognized.

On top of this I immediately get an E as soon as I key up into my NorCal dummy load. I also tried my 300w dummy and it tripped as well. I was using the 20m module, the RX trimmers were peaked, and the power source was a 9v battery at about 8.85 volts.

I didn't expect to have so much difficulty with this rig. I thought I could have it completed by the upcoming holiday, but now it looks like I will be spending some of it debugging and checking more solder joints.

For the band sensing double check the resistor pack orientation. If that's fine you can just plug a 10K or 22K resistor into the 3 and 5 pin locations and power up and see what the rig senses. If the plain resistor's are OK start looking at the filter boards for shorts across pads...

After fixing the band sensing problem, if your using a typical rectangular 9V battery try a more stout power source and see if the tripping stops.

For the band-recognition problem, double check that R44 is 22k (223). It's on the same side as the buttons, just above the LED display. For the transmit problem, check the circuitry around U12. Does it happen with every band module?

The judgment circuit of the band module is simple.
If resistance value is right, how will when I examine
voltage regulator? U9 and U10 are the same package.
Do not you make a mistake?

Thanks for the feedback everyone. I'll try these suggestions tonight.

The current trips on transmit on 80, 20, 17 and 15m. I did not try 30
& 40 due to the module recognition problem.

I was using the small square 9v battery. I do have a 6 cell AA
battery holder, so I'll have to pick up some batteries on the way
home from work.

40 coming up as 80 would imply the band select resistor is open, likely a bad solder connection to it or the pins on the plug. 30 showing as 40 might also be a bad solder connection, showing a little more resistance than it should. Higher resistance = lower band.

Check the connections to the 680 ohm resistor. If this is floating, it would take very little current to trip the reset.

From: Steven Weber
Topic: 2138 Message: 2144

I've had one of those Altoids chewing gum tins kicking around here for awhile and been wondering what to build into it all that time. The other day I thought to try fitting a L tuner into it. (do they still sell them? Haven't noticed recently)

I was able to more or less flatten out the curved bottom with a hammer, so now a piece of copper clad board sits mostly flat into the bottom.

A resistive SWR bridge and right angle slide switch take up about 1/4 of the length of the tin. A polycon variable is more or less in the middle and there is enough room left for another right angle switch and a couple of toroids. I figure on making it a two band tuner, 40 and 20.

Basically, its the same design as the ALT tuner, but half the size and a little less flexable. Its not quite finished (need to figure out the inductor values). I'll post a picture when its done.

Steve,

I think you meant "Higher resistance = lower frequency band". The
numbers of meters do get larger, which could be confusing.

I found that I couldn't get the band recognition to work really well on
80M until I put 100K in for RF1. With no resistor, I was getting "E"
even after waiting a while. Someone else pointed this out. The 100K
seems to make the circuit recognize the module much faster.

Are you cool with this change?

Thanks,

2149. Re: Interesting 3B Band Module Problem

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-17 04:38:54 UTC
From: Jim Fraser
Topic: 2138 Message: 2149

I switched the power supply to 6 AA batteries for tonight's testing instead of the square 9v battery.

>>> My 30M module is recognized by my ATS-3B as a 40m module and my 40M module is seen as an 80m module. <<<

As suggested I stuck a 22K resistor (40m) into pins 3 and 5 of the band module socket, but the 3B still sees 80m. I verified the proper values were installed for R44 as well as R35-R38 and touched up the solder joints. But the problem persists.

>>> I immediately get an 'E' as soon as I key up into my NorCal dummy load. <<<

I verifed the values of components and touched up the solder joints in the Current Detector circuit including the 680 ohm resistor Steve mentioned. The result was unchanged. I switched to a straight key and found that I could key down for quite a while (10 to 15 sec) with no tripping. But as soon as I released the key I got the 'E'.

I also noticed that the voltage read on the NorCal dummy load was 0 vdc, no power output. Since I had recently built the dummy load and have not used it, I dug up my HiMite-20 QRP rig and the dummy load showed 350mw output which confirms what I saw on a borrowed QRP wattmeter some time ago.

I did notice about a 20v spike in voltage at the dummy load when I released the key, but probably just noise.

Oh well, tomorrow is another day. Think I will try removing the above mentioned band module resistors to measure the values out of circuit, replace the SIP pins on the 40/30 modules, and replace the band module socket if the problem persists.

Jim,

Did you go through the procedure in the manual to get to this point?
In particular, do the two linear regulators read 3.5 and 5.o volts,
and you've verified they're not mixed up (swapped)?

I doubt there's anything wrong with the SIP pins or the band sense
resistors. You can test those with a meter on the pins (3 and 5) and
verify the path on each module.

You might try measuring all the voltages on the controller (U6,
MPS430) - see the chart in the manual.

If the rig thinks a 40M module is an 80M module, it should transmit
signals for the 80M band; but if that filter is really for 40M, you
won't get correct operation of the final stage, to say the least.

Did you check the operation of the keying mosfet Q6 per the
procedure, and then have you installed L3?

Just asking the obvious - you may be past that point.

Based on this I don't think its the band modules. I
would continue to double check the main board.

In thoery, it shouldn't be needed, but it will keep the A/D converter input
from exceeding the internal reference supply of 2.5 volts by too much.

Steve,

I can't see why it's needed either...but I saw this pattern where if I powered up the rig with the 80M module (with no band sense resistor), it gave me an E. When I pushed the menu button and reset the error, the rig still wasn't on 80M.

I found that everything would work if I let the rig sit unpowered for a while, maybe a minute of so. Then I tried 100K and it behaved like it should.

No big deal, but a mystery to me.

Thanks

Yes I have been following the procedure steps in the manual and I am now up tp the Band Filter Test and Adjustment. I did do the step with L3 removed but I did make an assumption that perhaps was wrong.

During the check of the keying MOSFET Q6 I saw the voltage rise during the DAHs but it dropped during the gaps between the DAHs. Should the voltage have continued to increase up to near the supply voltage until I stopped keying altogether?

I will go back and triple-check the 3.5 and 5v outputs and check the voltages at U6 as you suggested.

The reference oscillator is set to 10MHz and I got the local oscillator setup with some help from W1MT.

Many Tnx Carey,

Topic: 2155 Message: 2155

Steve,

I just finished making some measurements on the bandwidth of the entire ATS-3B. Essentially I moved the RF signal in 20 Hz steps and measured the audio output. Of course I found that I had to keep the RF signal below about -87 dbm to avoid AGC action - the AGC is very effective at higher levels. The rig is quite narrow. It's down 30 db about 225 Hz from center (30 db bandwidth 450 Hz). The 10 db bandwidth is about 250 Hz.

I found that the bandwidth is affected by whether I had an audio load on the rig or not. When I measured the audio with just my old HP400D AC voltmeter (Hi-Z), I got a wider, more symmetric plot than when I did a similar measurement with a 27 ohm load from the audio line to ground.

With a Hi-Z audio load I measure the rig's 6 db bandwidth as about 200 Hz. With a 27 ohm audio load I measure the 6 db bandwidth as about 100 Hz, and the peak is shifted down about 60 Hz.

This morning I measured some earphones - I found that several of them have an impedance of 16 ohms per side, which results in 8 ohms with both sides in parallel; these are small, in-ear Walkman-style phones. I have another more traditional set of modern phones that measures 56 ohms per side, for 28 ohms in parallel. I measured with a scope at 600 Hz, with a low-Z generator, and selected series resistors to match the phones. It's interesting that the AC impredances agree closely with DC measurements for 3 pairs of phones.

Clearly the bandpass filter characteristics of the output amp U3B (LM4808) are affected by the load. What's the "best" load? I've noticed that tuning across the passband sounds different when I adjust my inline headphone volume control. I measured the headphone control and found that it adds 500 ohms in series with each side, when set for minimum level, or 250 ohms net. So probably the rig is seeing around 100 ohms when I have the control turned down part way, and 8 ohms at maximum.

I noticed some time ago that the sound was different through the QBSA's amp - I see why now - the input to the QBSA's audio is high-Z. This makes the overall rig a little less selective, with a broader peak. With the low-Z phones, there's about one or two 50 Hz clicks of the Up-Down buttons where the rig sounds peaked.

Maybe the rig setup procedure needs to be done with the intended audio load hooked up, since the peak shifts a bit.

I'd appreciate any information you can provide on the audio design and the intended load impedance. I'm wondering if it's worth making a connector to wire the two headphones in series instead of parallel, etc.

The ATS audio filter is very effective at reducing noise and hiss, and it's superior to what many other rigs have. I hope I'm not opening a can of worms here - I suspect other people have noticed some of these little differences in the sound.

Thanks & 72

I uploaded some pictures to a folder with my call (K5MO) of my version of this fun little rig. I found a wallet tin just large enough to hold the rig plus all band modules with the lid shut.

http://ph.groups.yahoo.com/group/AT_Sprint/photos/browse/d6e3?c=

Being a boatanchors fan, I had to add some Hammertone paint. :-)

Nothing special, just another version of this fun rig.

wrote:

Steve,

I just did some more tests and realized that something I said earlier
is backwards. I did my bandwidth tests at 7.030 Mhz, and the LO is
on the lower side, near 2.115 Mhz, so RAISING the RF frequency LOWERS
the beat frequency (tone we hear).

This means that when we load the audio with low-Z phones, the audio
peak narrows and shifts UPWARD in frequency. The effect is a little
more than one button click. Sorry for the mistake.

I just did some listening tests - I dropped 10 ohms across the audio
output, while listening with phones set for about 100 ohms, and I
could hear the peak shift upwards. Using the volume control
definitely smooths out the peak as series resistance is added.

I tried running the two sides of the headphones in series instead of
parallel, to get 4X the impedance, and it did smooth the peak some,
but the audio level also went down, since the headphone amp sees a
higher Z load. So when I run the phones in parallel, I usually use
more resistance in series to cut the volume level; the peak is more
broad that way than with the phones in series.

There's also an effect running in series. In parallel, the phones
are in phase, and the sound seems inside my head, right between my
eyes. In series, they're out of phase, and the sound is in both
ears, not centered. I wonder if people can copy CW better one way or
the other...

I verified that the way my rig is set up, the side tone is the same
frequency as my audio center. This is how I like it, so I don't want
to change anything. The effect of the peak shifting higher with less
headphone resistance is small potatoes compared to everything else
being almost perfect.

The rig draws only a few mA more when the audio is so loud I can't
take it...super efficiency. The data sheet for the LM4808 is pretty
amazing.

2160. Re: Interesting 3B Band Module Problem

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-18 06:14:00 UTC
From: Jim Fraser
Topic: 2138 Message: 2160

SUCCESS!! Among other things I checked for solder bridges (again) under a very strong light and found a very thin bridge across pins 4 and 5 of U7, the 5v and 3.5v lines. There was also a bridge across pins 15 and 16 of U7. A couple days ago I had retouched this chip when I had problems with the reference oscillator and must have caused the solder problem at that time.

After the cleanup, all my band modules now sense correctly, the keyer works with no 'E' and I get power output!

80m - 3w 20m - 3w
40m - 2w 17m - 2.5w
30m - 3w 15m - 3w

These values are without any toroid adjustments, I'll do that in the next couple days. Power input was 9.18v so the output looks reasonable.

Thanks to W1MT, KX0R, Steve and everyone else for your assistance. Time to go toss down a couple cold ones and celebrate!

Jim,

Nice work finding those shorts! I think you showed that 3.5V chips can run on 5V and not burn out. Hope everything turns out OK.

Those power levels are like what I had at that point. 3W at 9.0V is plenty - that should yield close to 5W at 12.0V. Be sure to watch the supply current when you adjust the modules. Just because you can get even more power doesn't mean you should. 40M was my low one also - I ended up adding some capacitance to C2F.

I'm going to post all my results to the FILES section here in case someone else wants to see what I ended up with.

Great. Now you can help me locate MY shorts!? [ba-dum chsssh...]

2163. Power Output and Filter Details

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-18 07:10:44 UTC
From: radio_kx0r
Topic: 2163 Message: 2163

I just uploaded a pair of pdf documents to the FILES section here.

The file "ATS-3B Power Measurements" lists what I'm getting from my completed ATS-3B after adjusting the filter modules. I'm delighted that this tiny rig delivers this performance on every band.

The larger file "ATS-3B Filter Module Details" is a complete list with details for each module. Modifications are printed in red, so you can see what I messed with. Each band is detailed on a separate page for clarity.

Be warned that you can screw up your transmitter if you try to modify the modules for too much power. You can end up with excessive heating, too much current drain, loss of efficiency, and spurious emissions if you're not real careful. Read everything I wrote in the beginning before even thinking about messing with these things! Read what Steve says in the manual also!!

You have been warned...this is about my rig. Your results may vary. Your rig is your responsibility.

I confess this was fun.

BTW :

Those Altoids gum tins are just dandy for carrying some spare stuff
for your portable radio setup. I keep a spare set of earbuds, a few
spare fuses, some small wire-nuts, a few fishing snap swivels, a
couple of solderless banana plugs and a bit of fishing line for those
times where something breaks or I manage to forget something at home.
It is amazing how much small stuff you can pack into one of these
little tins.

Carey,

I saw your posting about the power levels and will pick up a capacitor to increase the value at C2F on the 40m module and see what happens. If I can get 3w at 9v on all bands for field work, I will be happy.

I think I will also pick up a 5.6K resistor for the current trip mod just in case I need the extra margin, though I won't add it unless I need it. I will be using the 3B with a BLT Tuner preset offline using my Tenna Dipper.

2167. Series Power Supply Resistor for Tuning

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-18 19:43:23 UTC
From: radio_kx0r
Topic: 2167 Message: 2167

Following a suggestion from someone else here, I tried putting a resistor in series with my 3-cell lithium ion pack, to reduce the current when tuning the rig. This works so well I can't see why anything else would be better.

I used three 20 ohm 2W metal oxide resistors in parallel - that gives a resistor of about 6.7 ohms. I put them in the box with the cells, and wired a slide switch to short out the resistor for normal full-power opration.

The rig's output is cut in half, from about 5W to 2.5W, with the cells fully charged. The current draw is about 0.5A with the series resistor. There's no effect on the rig's operation, except that it's a lot easier to avoid current trip.

The keying is surprisingly good with the resistor - you can go ahead and operate with it - this is contrary to everything we've all learned with other rigs. I did listening tests, and the keying's OK - clean, stable, no chirp, no clicks! I haven't looked at it on the scope yet, but I'm not worried about using it on the air.

Might be a way to extend battery life a bit in the sprints...

It sure makes sense to tune your tuner this way! Use 10 ohms if you want to knock it down lower. I chose 6.7 ohms because I'm already using a bridge on my tuner.

The ATS 3 had a slug transformer on the main board. It
also has wide mode. The ATS 3A does not. :)

> I am pretty sure that this kit is a 3A, but not completely. The
>board just says AT SPRINT III with KD1JV below that.

Then you have the original ATS-3, since its labled AT Sprint III

The ATS-3A board is labled ATS-3A
The ATS-3B board is labled ATS-3B

There is only one mod for the original 3. R22 on the back side of the board should be 270 ohms. Since you have a rev C manual, then you probably received that value.

It is not practical to add 17 meters to the rig. Besides having to get a new DDS reference clock, new DDS output filter, the AC version of the '02 logic chip, new firmware and another filter board, the 3 and 3A can only reconnize four different band modules.

Also, I do not have any spare filter boards for the 3, 3A or 3B. (so don't loose any of the ones you got, as they can't be replaced!)

>after so many cycles? Or do think the dip switch would even survive the
>RF passing through it?

Good question. Looks like most of them are rated for 100 ma and will need
to be used on the high current side of the inductor.

Although your 20/40 version sounds like an easier
>solution with tthe slide switch. Maybe then just use another halfwave wire
>for cut for either 30/17m if you want those other bands? I bet the tuner
>has the range to match 'em? Cool!!

Each band requires its own unique L/C combination. The ALT/SLT uses a bank
of 5 inductors which can be switched in or out to produce 64 different
combinations in order to arrive at the proper total inductance.

I used 0.5, 1, 2, 4 and 8 uhy values so any value from 0.5 to 15.5 uhy in
0.5 uhy steps can be obtained. Actually, for 40 to 10 meters 0.25, 0.5, 1,
2 and 4 uhy values could be better choice.

There is not enough room in the gum tin for that many coils. In the two
band version I'm building, the coil for each band will be tweaked by
adding/removing turns to get the right value with the antenna wire
attached. Once that is determined, the coils will be left alone.

Jess,

Research mods to the ATS-3 - there were a couple that required some interesting component placement/additions. Very good rig !! Also, since it has the wideband mode and newer versions don't, it has features that others may desire. Of course, it doesn't give you 17m. I've built three of Steve's AT rigs (ATS, ATS-3, and ATS-3b) and they have all been fun.

2195. November NAQCC Sprint

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-20 03:01:44 UTC
From: Larry Makoski
Topic: 2195 Message: 2195

This Wednesday evening, the North American QRP CW Club will be holding its monthly sprint.

Here are the particulars:

Date and time:
Thursday November 22nd, 0030-0230 UTC
(Remember that's Wednesday evening here in the USA) That's 8:30 - 10:30 EDT, 7:30 - 9:30 CDT, 6:30 - 8:30 MDT and 5:30 - 7:30 PDT.

Bands - Frequencies:
80M - 3555-3565 kHz (Be courteous to FISTS operating on 3558 kHz)
40M - 7039-7050 kHz (Avoid W1AW on 7047.5 kHz).
20M - 14059-14065 kHz. General:
A particular station may be worked once on each band. Operate CW only. All licensed amateurs are invited to participate, but only those operating QRP (5 watts or less) are eligible for awards.

Call: CQ NA

Exchange:
RST - SPC (State Province or Country) - NAQCC Nr.
(non-Members substitute power level for NAQCC Nr., e.g. 5W, 1W, etc. Be sure to add the W.)

QSO Points:
QSO with a Member, 2 points.
QSO with a Non-member, 1 point.

Multipliers:
Each USA state
Each VE province
Each country except W/VE
All multipliers count only once in the contest.

Bonus:
If you use only a straight key for the entire sprint, multiply your score by 2.
If you use only a bug for the entire sprint, multiply your score by 1.5.
If you key with anything other than a straight key or bug, there is no bonus multiplier.

Categories:
SWA - simple wire antennas - for those using a simple wire antenna per NAQCC definition.
GAIN - gain antennas - for those using other than a simple wire antenna.

Special Award:
Our special award this month goes to the one who has the highest score and uses a homebrew straight key. If a 1st or 2nd place certificate winner also qualifies for winning the SA, the SA goes to the next highest scorer. That is because we want as many members as possible to receive one of our certificates. You must indicate in your report if you are applying for the SA, and include a picture of your straight key.

Autologger SA info: To be eligible for the SA, you must select Yes in the 'Eligible for the Special Award.......' box. Nothing need be put in the 'Special Award info.......' box. You will have to submit your key picture in a separate email.

Prize:
Continuing this month we are giving away a set of CD's to one participant according to the following rules:

1. The participant meeting the requirements below and posting the highest score will be the winner of a set of CD's in the following months: July, August, September, October, November, January, February, March, April, and May.
A. Requirements: The participant must be a NAQCC member and can not have won a CD set previously.
B. If the highest scorer does not meet the requirements, then the CD set winner will be the next highest scorer who does meet the requirements.

2. Twice a year - in the December and June sprints, the winner will be a participant drawn at random who meets the requirements in 1A and who makes at least 5 QSO's in the sprint.

3. Club Officers (WY3H (ex-KB3LFC), K3WWP, W2LJ, K5DUZ, KD2MX) are not eligible.

REMEMBER: You HAVE to be a NAQCC member to be eligible to win the CDs; and there's still plenty of time to join before Wednesday night's sprint. To join the NAQCC, please visit:
http://www.arm-tek.net/~yoel//joinup.html

Entry Deadline:
All entries must be RECEIVED before 2400Z on November 28th, 2007. So submit as soon as possible, especially regular mail entries.

NEW! NEW! NEW!
Be sure to use the new NAQCC Sprint Autologger feature! Please visit http://home.alltel.net/johnshan/sprintlog.html after the Sprint to send in your entry!

For further information, please visit:
http://www.arm-tek.net/~yoel//sprint200711.html

2196. First Field QSO's with ATS-3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-20 06:40:12 UTC
From: radio_kx0r
Topic: 2196 Message: 2196

It was a warm afternoon here, so I hiked up into the woods with my ATS-3B for its first use outdoors. The sun sets early, so I didn't mess with a dipole - just a half-wave sloper for 20 meters up 25 feet or so in a pine tree. It connected to a BLT sitting on a log, with a 45-foot counterpoise lying in the grass. No feedline - no ground.

The BLT tuned up fine in Hi-Z mode, and I got a good null. The band sounded too quiet, and at first I thought the band might be going dead - but before long I heard WA5PRI calling CQ, and we began a 45-minute rag chew from CO to Thibodaux, LA. It was pretty solid and pleasant right until the band fell out - sunset was somewhere near mid-path, and there are no sunspots.

Right after we signed a local ham on an MFJ indoor loop called me from about 6 miles away. He was 599+ - we were line-of-sight from my elevated site on a mesa.

Anyhow, the rig performed perfectly, it was easy, solid as a rock, an amazing experience to use. All I could say was "WOW". It's a lot easier to use than it is to build!

Later I modelled the sloper on EZNEC, and found that it was down almost 12 db compared to a dipole at 35 feet, in the direction of Louisiana. It was still a good QSO. It helped being on the edge of a mesa, and the LA station had a beam.

The end-fed simple antennas offer simplicity, fast setup, and a minimal amount of stuff to carry. They don't model very well compared to horizontal dipoles, loops, vees, and EDZ's. Classic tradeoffs here.

My BLT is overkill. I may build one of those L-network tuners just to play with it. To go really tiny, a mica variable might be worth considering - another trade-off. When the polyvaricons dry up, we'll all be looking for alternatives.

Hey Cathy (I *think it is Cathy, the message seems unsigned) and the gang;

Here's what I use to avoid placing the current node of the antenna near
the ground, where a portion of your signal goes to "heating up the dirt":

1/2 wave of wire connected to a 1/4 wave of balanced feeder. It looks and
acts just like a j-pole. In my case the feeder line is the real thing,
i.e. some surplus N.O.S. balanced feeder, but you can use whatever might
be handy, including "window line" if it doesn't get wet. If you get this
cut just right, you don't need much, if any, tuner btw.

You can use the 1/2 wave portion as a sloper, horiz. dipole, inverted v,
or even a vert.

Slopers are great btw, and will work even better without the so-called
counterpoise.

Before I got my Li-poly batteries, I usually ran my original ATS-3 in the Spartan Sprint with a single 9v alkaline battery. I think a -3B draws pretty close to the same current. During the two hours I usually alternated hunt-and-pounce with CQ'ing, and could make a dozen or two brief contacts. There was still enough juice at the end of the sprint for over 1 watt output. But I think a pack of AA's has a better QSO's-per-pound ratio, if you're not limited to two hours.

My results have been much like Bill's. A couple of hours and 10 - 20 short QSOs was about what I could expect with the ATS-3A on a fresh battery. Not bad for a quick, light outing. But I also agree that 6 AAs are ultimately the better bet. Like Steve says, 9V is the "sweet spot" for the ATS-series rigs.

Bob,

Do you connect your 1/4 wave of balanced line to the end of the half wave wire, with one side of the balanced line unterminated at the top end?

That is the classic single "zepp" arrangement that's been around a long time. It's always been hard to understand, but it certainly works. I want to try it outdoors when I get a chance!

Or are you doing something else?

The motives for the direct connection with no feedline are simplicity and less stuff to carry. While it doesn't work as well as some other arrangements, the direct connection eliminates a quarter wave of feedline. This line - ladder or open - takes up almost as much space in a daypack as my entire rig, even for 20M. It also makes the operation visible to others, while a black wire in a tree is almost invisible.

The reason the end-fed half wave sloper is several db below a dipole is that most of the power goes up at high angles. This antenna is a cross between a half-wave vertical and a low half-wave dipole. By feeding the halfwave at the end, the current at the feedpoint is very low, and if the counterpoise is near 1/4 wave, or a multiple, it carries and wastes very little current. I tested this with several EZNEC models. The antenna has a broad azimuthal pattern, like a cardioid with a shallow null, with several db more signal in the direction opposite the high end of the antenna. The antenna has poor low-angle performance - the pure vertical arrangement has a lower-angle lobe - and most of the pattern is into the sky. For 20M it's not a great choice, even though it worked for me yesterday. However, for the low frequency bands it's a better deal, since we often have and enjoy high-angle propagation.

It's fun to experiment.

Mike,

I haven't heard anyone say they were sorry for using lithium or NiMH rechargeables with this radio. It runs well from 6 to 12V, so you have many choices. Rechargeables cost much less in the long run, especially compared to 9V alkalines. Rechargeables have some other nice characteristics.

The number of QSO's depends on what you call a QSO. A contact in a contest doesn't take much energy. On the other hand, rag chew for an hour with 5W, and that Altoids box will get warm.

Many hours of ragchewing are possible with 2 or 3 18650 lithium ion cells (about 2 AH). My 3-cell lithium battery weighs 7 oz including the case, etc. Sorry, but I can't see a good reason to run this radio on 9V one-way batteries. If you don't want to get into lithium, shop around, and you can find good NiMH AA cells for about $2 per cell. The AAA's will run this radio a long time too.

There are lots of previous posts on this topic here - just search.

Similar to the zepp. Although many different coupling arrangements have
been attributed to the zepp, enough that this is somewhat clouded.

Again, your antenna has current node(s) that are close to the ground. The
'j-pole' eliminates that issue. As such the 'j-pole' will radiate "better"
than what you are doing.

If you decide on a sloper, regardless of why or even what the radiation characteristics are, keeping any ground nodes from being near the physical ground ALWAYS helps in the strength of the overall radiated signal field. You are correct that the end of a 1/2 wave is a VOLTAGE node. The overall point is that this is a better node to place low/closer to the ground as opposed to a current node. Adding a counterpoise wire to lower the attachment impedance (instead of a transformer,) puts CURRENT node(s) closer to the ground, and this can be a real detriment for any antenna configuration.

BTW, the 'transformer' can be a 1/4 wave matching section, a coupled 'tank circuit', a z-match or even a two element tuner with sufficient range. The open wire transmission line I use is very high q., so it is perhaps the most efficient. Unlike window line, it is marginally heavier and bulker. It is not even as heavy as the coax used in a center-fed dipole.

In summary;

A sloper without the radiation/pattern issues of the (extra/unwanted) counterpoise is a great antenna.

An additional advantage to the "j-pole" is the ability to hang it the other various configurations at will, as the 1/4 wave transformer allows you great positional leverage -> i.e. you can get this hung just about any-which-a-way, including as a horizontally oriented dipole, albeit 1/4 wave high.

From: mpupeza
Topic: 2205 Message: 2205

Hi;
I've just received one of Steve's last of his 2nd batch run of the 3B kits. Yippee!
Now a question!
How do you separate the filter boards?
I see that they're scored and I assume that you just snap them apart!
However, as I was flexing it, there seemed to be no real tendency to break at the scoring, so I quit.
Now I'm the guy that even toilet paper fails to separate cleanly at the perforations, same with paper towels, so you see why I'm nervous!
Also, I've decided to solder the parts individually! That way I can only screw up a small section at a time, rather than the whole board!
Advice appreciated.

Mike,

Yes they just "snap" apart. With the score line toward you gently bend
away from you.

Good Luck

Snap them quick.

If you are still timid, align the scored edge up with
a sharp counter edge and use your palm to snap them.

thanks to you all the the feedback. i'll certainly be going with a 2-3 cell lithium setup. but the ability to do something with a buy-it-anywhere-you-are 9v alkaline and still do something meaningful is really neat.

i finished up the qbsa last night. will now get back on finishing the 3b. it sure is amazing, it's even more intriguing than my k1, which i also enjoy.

2210. Nice label uploaded to "Generic ATS3B Label" in Files section

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-20 22:42:41 UTC
From: kc7fys
Topic: 2210 Message: 2210

He's being subtle about it, but there's a very handsome label for the
3B just uploaded to the Generic ATS3B Label folder in the Files
section. JN1GLB has designed a good-looking and informative label that
would look good printed on transparent film or opaque paper.
Nice work!

2211. An additional run of the ATS-3C ...or D?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-21 01:29:44 UTC
From: tf3kx
Topic: 2211 Message: 2211

I presume the ATS-3C is sold out. It would be good to hear if an additional run of this model, or possibly the next one, is on the plan somewhere.

I am deliberating if I should continue saving up for a K2 or go for the ATS when they become available...

Steve,

I can't seem to find those files.

Mind posting the direct link to them or even reposting the files?

Thanks,

Hi,

He had mentioned about the possibility of a 3rd run
of the 3b after the holidays. I imagine getting the
parts together for the first 200 kits must have been
quite an undertaking. To my knowledge, I haven't
heard
of any plans of a 3c yet.

3b is currently out of stock. May be more next year.
That's up to Steve.

As far as the K2. Save up and get it! Then when Steve
kits another round of ATS rigs, get it too.

I'll most likely offer them again next summer. Why so long a wait? I'm planning on another AT hike in the spring and will be gone all of April and May. December is a wash out with the holidays and such. Nothing ever gets done in December. Next thing you know its the middle of January. It takes me 4-6 weeks to collect parts, sometimes more if something is out of stock and back ordered. By the time everything is ready, its time to go on the hiking trip!

I think we've taken the ATS rig concept as far as it can go and still fit it into an Altoids tin. Therefore, a C or D version is not likely. The next major design project is for a little 20 to 10 meter SSB rig. I've been poking at it on and off, but am not in a big rush to get it done. There will be no great demand for it until we get some sunspots, hopefully in a year or two! It will be nice to have a rig like that ready for when the cycle starts to pick up.

Thanks, Steve, for the update.

I can wait till summer. I'll start saving my pennies now in anticipation. My finances were strapped at the time you made the first two runs of the kits.

Lettuce no your hiking plans. I'll try to work you. It was great working you from Virginia during your last trek along the AT. I was operating WQ8RP and was very surprised at the "VA" in the QRPTTF exchange!

2219. NR4E filter mods to ATS-3

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-21 05:59:27 UTC
From: DOUG PHILLIPS
Topic: 246 Message: 2219

Guys,

I finally got around to installing Craig's mods to my ATS-III, the one prior to ATS-3A and ATS-3B. If any of you have an original 3 do the filter mods, very nice sound coming out of the head phones this evening. Details are on W1MT's web site:

http://w1mt.qrpradio.com/filter.html

I have an extra mod kit if anyone wants one and I think NR4E still has them available also.

Steve,

We really appreciate your offering these amazing kits. Please enjoy your hikes and continue being creative. I think the ATS-3B is almost perfect for what it's meant to be, and it wouldn't surprise me if you could sell some more of them if you choose to.

I'm interested in your HF SSB rig concept. When the sunspots return, SSB will provide lots of thrills for low power operators. SSB has some different qualities - like you can tell people you're portable, etc. quickly, ask questions fast, move the qso along, whatever.

Whatever you come up with will be interesting to many of us. Thanks for sharing your thoughts on what you're working on.

2234. Re: An additional run of the ATS-3C ...or D?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-21 19:55:11 UTC
From: tf3kx
Topic: 2211 Message: 2234

Sorry folks, I was somehow mistaken that the latest version was 3C.
So, the real question should have been when a second run of the 3B
(or a new 3C) would be available.

Thanks for your replies, Steve - wish you all the best for the
holidays and your hiking in the spring. If you have a list of orders
for the next kit, you may add me to it.

Topic: 2230 Message: 2236

Hold on there! Think about what you are doing.
When I completed my BEE I thought about writing a review on EHam but before penning such I gave it some thought.

Remember last winter/early spring when Steve mentioned that he had an updated version of the ATS? Then as conversations and guesses about the configuration rampaged, Steve went on "walk about". Meandering about the trail having a good time communing with nature and wearing out boots while we waited ... and waited.

I am certain that Steve's pleasure during this period was diminished a bit knowing that he left us all hanging on tender hooks. Given the fact that the Bee is sold out and won't be renewed until after Steve's next sojourn into the forest do we really want to burden him with all of that guilt worrying about all those folks who read the review, would kill to get their hands on a kit and there are none to be had? Can you imagine the responsibility? That would be a cruel thing to do to poor Steve!

OH WHAT THE HECK! Go ahead he'll get over it.

72,
Ran

I'll give up my Bee when they pry it from my cold dead hands!

Hi Terry,
The calls are WB9ZUV and WC7S
The one for WC7S is a 3.... no b..*sigh*
The one for WB9ZUV is a 3 also. However, he is planning to get the 3B in the second run, and I will too.
Since Steve isn't going to make a 3C... I think I will get the 3B and call it good.

Thank you Terry, you do those labels very nice!

Terry, I've thought of doing that. I have an old HW-7 that's been modded to Hades! I've thought about just emptying the case and installing an ATS-3 or 3b (I have both), frequency counter and rotary encoder. Maybe even using the original band switches. I'd have to come up with a scheme to use 3 band switches to switch 6 bands, maybe using the xtal switch to effectively make two sets of 3 band switches. I have so many other projects right now that it'll probably have to wait til summer or so.

There's only one problem. The transmitter doesn't seem to like long leads
running to the filter. I tried making a relay switch filter module once and
the PA didn't like it at all.

Hmmmmmm,

Sounds like one would need to mount the whole 3B board upright in a box with a "leetle" door/window to extract the filter manually still.
I expect the control buttons/jacks wouldn't be a problem if they required leads. Integrating it all (with the QBSA) in one enclosure would be the trick.
Perhaps have a storage "rack" inside, easily accessible for the filters so it would not be that much trouble to pull them out and replace.
This could be pulled off with the current hardware.
The only issue would be the layout inside the box and possible fabrication/modification of a stock enclosure of some kind. Could consider different antenna connectors. With extra space in the box, might be able to have a filtered power supply to plug into the wall although that would not be necessary if one had one of those $60.00 12v power supplies that one can dial the voltage and current up to 15V and 3 amps and everything in between.

Hi, Terry:

Your idea would resemble an upgrade of my olde, trusty, Heathkit HW-9, which keeps plugging away. Don't remember how the HW-9 receiver does, but it seems to have a "reasonable" front end. It did "reasonably well" during several Field Daze back in the 80's when I was more heavily into QRP contest mode. The HW-9 probably uses more milliamps on receive, and possibly on transmit. I haven't measured those parameters recently, but I do know it runs nicely for 24 hours on a fully charged large marine battery during Field Day, so it would do okay for portable operation. :).

The HW-9 was built before the direct digital sympathizer was common, so it has a "regular" VFO. Mine covers 80 thru 10, including all the WARC bands. It is a "nice size" for portable operation, and not bad for desk operation. Kinda bulky if I want to set up on a hiking trail, though. :) That's what is intriguing about the ATS... I've lugged my Drake TR-7 or TR-5 out on Field Expeditions, and that's a LOT of weight. The HW-9 is much easier to carry, but it's still much heavier and bulkier than a rig which fits into an Altoids Tin.

If I were designing an "ideal" mid priced desk rig, I'd look very carefully at the circuit of the Elecraft K-2. That rig has lots of "bang for the bux." An "ideal low priced desk rig" is an oxymoron in my way of thinking.

According to a review in QST, the HW-9 with the WARC bandpack cost $290, so it probably would cost >$500 in today's dollars. That's considerably more than $190 in today's dollars, and would make me think hard about a K-2 if I were in that kind of market.

One way to switch the band modules would be to use the old turret tuner from the RCA tv sets. Use the same turret, same contacts, same detent, and box. Replace the existing circuits with the band modules, and you have a band switch. Shouldn't take very long at all. Big problem would be to find the old tv sets.

2246. ATS3B - first QSO's

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-22 01:03:43 UTC
From: Fred Maas
Topic: 2246 Message: 2246

With the receiver working well, the crystal filter aligned, it was time to transmit. I used a 9 volt battery that had deteriorated to 7.6 volts according to the ATS3B annunciator. I used my 80 antenna which is the tower, tuner telling me that it was showing the radio 1.1:1. I am in Santa Fe, NM

Tuning down from 3.560 I found N9JF/m calling CQ. He responded and offered 559, clean keying.

Tuning further down to 3.551 found AE5L finishing a QSO and gave him a call. he gave 559 and clean signal, and we chatted for half an hour. He was in Tulsa, OK.

Next, on 3.549 came a half hour chat with AC5P. Mike also said I was 559 and with clean keying. We chatted for some time.

Then WD9FJL in ABQ, NM called me.

After all those QSO's the battery display said 7.4 volts. I have no idea what power out actually was, but the rig was certainly working.

I tuned further down and found many DX stations. I just know they could have heard me, especially HC8N who was very strong, but I could not rattle pile-ups on them. Even on 80 I have worked all over the world QRP, and just know can get them. Will try on the weekend.

This rig is a real blast, thank you Steve for making it available for us kit builders!

72 and happy turkey day.

2252. ATS-3B and QBSA

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-22 23:01:52 UTC
From: radio_kx0r
Topic: 2252 Message: 2252

Happy Thanksgiving All!

I just hooked my AST-3B up to my QBSA, and it works! It counts and updates well on all six bands.

My LO connection is to C28, which is the unused output from the DDS. This is a convenient point. I soldered a 4.7 pf cap to this.

I mounted a micro phone jack about an inch behind the RCA antenna jack. A short piece of small RG-178 coax connects the new LO jack to the 4.7 pf cap. The coax shield is tacked to the grounded end of C28.

My cable to the QBSA is made of RG-178 and is 21 inches long. I used a micro phone jack on the QBSA also. You could use any convenient small coax connectors and cable.

The new battery measuring feature is useful for checking the variable voltage from the QBSA.

It will be fun using this combination at home -

Thanks Steve

Hi,

Steve had mentioned the prospect of maybe doing
another kit run of the 3B after the holidays. I think
if folks still want one, they should make it known so
Steve has an idea how many kits to do.
On the other hand, if he has some new ideas, he
might
come up with something else. He did post the 3b was
about as far as he could go with this form factor.

2256. Red Plastic for the Display

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-23 20:55:51 UTC
From: radio_kx0r
Topic: 2123 Message: 2256

After getting my QBSA running with my new Bee, I decided to try making a faceplate from the same red acrylic I used to make a filter for the Bee's display. This project turned out pretty well. The QBSA's display looks better, so it's more fun to use.

Making the faceplate was easier than mounting the QBSA in the BLT case. I used a small hacksaw, a file, a square/ruler, drills, and a tap. Fortunately, it was unnecessary to remove the QBSA from the case. I'll eventually replace the screws with black ones.

Photos are posted in the "PHOTOS" section of this site.

2257. Re: ATS-3B and QBSA

Yahoo group: AT_Sprint (2002 — 2008)

Topic: 2252 Message: 2257

Congrats, Carey. I have been ironing out a couple problems with my QBSA. Last night I found a very tiny solder bridge on the rows of pins to the display board. Ths was causing my display to show 30.00MHz instead of 10.00MHz when the Freq Input was connected to the ATS-3B TP1 in calibration mode.

The second problem was that I was getting the same power reading in both forward and reverse. Then when swapping connections as per instructions both power levels were 0. After verifying parts, transformer winding, checking for bridges and swapping in another LM358, I finally saw the problem. The dummy-butt (me) who soldered on the BNC connector for the Antenna soldered both terminals to ground! This from a guy who used to be an electronic tech having built complex prototype boards! Glad I don't do this for a living anymore (now a software engineer). I was then able to calibrate the forward and reverse levels at 3 watts.

I can now put the QBSA into the enclosure I have already prepared, and then get started on the enclosure for the 3B. Now I can enjoy the rest of the weekend!

Date: 2007-11-24 16:35:41 UTC
From: n0tu/Steve
Topic: 2258 Message: 2258

My BEE is ALIVE (and well I think?)!

Just have to share my BEE happy dance! Made my 'first-QSO' on 40m w/K7RJ last night. Band was just starting to go long. CQWW DX-test was getting off to a roaring start! Some where between all the QSB and QRM I managed to squeak in an exchange with Ron before all hell broke loose from CQWW.

Looks like without any L1/L2 tweaking she's doing ~3.5w @11v:
http://picasaweb.google.com/n0tu.qrp/HBqrpRIGS/photo#s5136419212311213218
Haven't checked what's normal yet but this is plenty RF to keep me happy. I've yet to do the CAL and fine tunning steps and build the rest of the modules which should be fun now that I'm over the hump of the basic 'turn-on' stage! (whew!) Not to mention packaging and rethinking my label! This new firm ware is gonna take some time getting used to the new functions and where they live (for me anyway?). Can't wait to get out there with this BEE for a real 'in-the-field' first-QSO. Especially now with 17m this will be FUN to explore!

I'm sure happy with my results thus far! AND Sure glad this group is here! Man it's been a huge boost to be able to monitor, glean insights and gain encouragement from! - A Big Thanks to Steve for (yet another) GREAT design & kit and the rest of you for sharing!

Hey Jess, Man if you've built all the gear you say you have I wouldn't think twice about diving into the ATS construction! It's really not that bad. Granted it's tiny parts. BUT if you've got patience, maglamp, good lighting, and a small tip for Weller you're in business. The rest is just perseverance! And Steve won't let you fail! Like Elecraft he's there if you get into trouble while trying to debug it.

It's worth it to do it yourself ...really!! Even if I had the time to do another ATS I wouldn't want to deprive you of the pleasure (not to mention the happy dance) that comes from completing an ATS! You CAN do it!

OK, how about if you start it and If you REALLY get into trouble and realize this SMD stuff ain't for you ...give me a call! Steve/n0tu

Congrats on the BEE Steve!

And thanks for sharing the pictures.

You always seem to have good shots even close ups on your bench are
ultra crisp. May I ask what camera you are using? Did you do the
bench shots with the camera on a tri-pod or just free hand?

2263. ATS3B Trial by CQ WW (or, 60 minutes of DX)

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-24 23:40:56 UTC
From: Fred Maas
Topic: 2263 Message: 2263

IT WORKS

Since I am not confident that it is tuned up adequately (no output meter sensitive enough for the job) I have been using a 9 volt battery. It started at 7.5 volts (that would be about 1.5 watts output), and ended about 6.7 volts, likely under one watt.

call sign W5YA (op: kt5x)

Put the radio for the first time on 15 mtrs for 30 minutes and worked:

ZL4PW
AH7C
KH7Y
KH6YR
KH6MB
KH6LC
VE3EY
KH7X
HC8N
KL7WV
KG6DX
E51A

Then, after running about four miles on a perfect afternoon in the light snow, about 30 degrees, couldn't have been nicer...

tried the radio for the first time on 20 mtrs for about 30 minutes and worked...

JF2QNM
JI1RXQ
JH8SLS
KH6YR
PS2T
XE1MM
JA1BPA
VE6EX
JA1JKG
JN2AMD
JH3AIV
JA3AIU
JA3YBK
JA2ZJW
VE7SV
JF1SQC

Most of these were one call. Most of them were solid S-9 here in New Mexico.

tuning the rcvr with the buttons is soon comfortable enough. It is quite resistant to overload and IMD, had no particular problems,

Must rig up a current limited supply source so I can stay on a while!!!

72, FD - kt5x

wrote:

Yes, Fred, the radio works, but the poor little thing is almost
starving. It works even better with a little more voltage and
current....

My first 5 contacts on 15M today were:

ED8A 33
ZF1A 8
PJ2T 9
ZS4TX 38
HI3A 8

These were with either a loop antenna or a small Vee, both at 35 feet.
That's a nice way to start out on 15.

I agree with Fred about the minimal overload. KW stations right in
the passband do take over, but I can't tell they're on the air a khz
away, unless they have clicks. Local QRO contester K0RF is a few
miles away, and he does some serious damage sometimes - but on the
Bee, he's only a problem within 1 or 2 khz.

Built the voltage limiter with the parts you sent me, thanks! I cut
the 13.5 volt supply to 10.67 volts and now running perhaps 3 watts.

I don't have the 40 mtr module built yet, so playing on 80 mtr. I am
having no trouble copying Europe (from new Mexico) in the 3B.

And i have worked KH7B, CN2FB, VE7GL, ZF1A, KH7X ... so far ;-)

Steve

Did you add the extra 22K chip resistor across C58?

Steve Galchutt <n0tu.qrp@...> wrote: Woohoo ...I hear and see the blessed 8s also seeing the 3.9 V at TP1!
....YES, YES ..oh YEES! AND I hear those lovely dits/dahs with a paddle plugged in! heh.

BUT if I power up and down right away I get an "E" on the LCD? However if I wait for a couple of minutes then power up I see and hear the 8s again! Donno what this means? But I can also step through the menu functions and all is well!

I hope this is all good news?

2271. batteries for ATS3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-25 23:47:52 UTC
From: Fred Maas
Topic: 2271 Message: 2271

Contemplating power source for the ATS3B ... in its intended service, which is to carry while ultra-running in the Rockies. Most of my runs are from two to six hours at altitudes from 9,000 to 14,000 ft.

9 volt alkaloid

E-flite LiPoly is 11.1 volts, 860 mAh, 2.4 ounces, $40, and needs a special charger, careful handling

another LiPoly was 2100 mAh, 6 ounces, $70, etc.

but here http://www.nimhbattery.com/9v-ultralife-batteries-9-volt.htm

is a 9 volt, 1200 mAh, 1 ounce, for $5.

Has anyone tried these? Do they hold up under the relatively high drain moments transmitting?

Does anyone have better idea for small and light???

72, Fred kt5x

2272. Re: batteries for ATS3B

From: n8xx@arrl.org
Topic: 2271 Message: 2272

I'd say this all depends on how much you value weight, and how much you'd value the fact that the fact that the LiPO and the NiMH cells are rechargeable.

It wouldn't cost you much to try the non rechargeable ones, just to see how they hold up. They're considerably lighter than the rechargeable ones.

72/73 de n8xx Hg

p.s. Running @ 14000 feet is beyond my capability - even when I lived in Denver for 5 years. Congrats on your athletic ability! Now a daze it takes me 3 or so daze to get used to 9000 ft altitude in Breckenridge where we like to go for vacation.

2275. Re: ATS3B Trial by CQ WW (or, 60 minutes of DX)

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-26 02:39:57 UTC
From: radio_kx0r
Topic: 2263 Message: 2275

-
Reading about someone else's DX can be boring - so you can skip this if you hate DXing. Fred and I both worked a bunch of DX with our BEEs this weekend. Now Fred can smell DX, so I'm not surprised...

The CQWW was a nice test of the ATS-3B. The BEE's not designed to bust pileups, but it can be heard in some amazing places, if you can get the other op to listen.

My BEE made dozens of DX contacts on 80, 40, 20, and 15 meters. I only tried 80 for a few minutes, and I got CN2FB (33), KL7WV (1), and VE7GL (3). On 40 the DX was piled up, but I managed to work LU4MHQ (13), EF8M (33), EA8/OH4NL (33), KH6MB and KH6YR (31), as well as a bunch of Caribbean and Canadian stations.

On 20 and 15 the QRP DXing was amazing: ZS4TX (38), ED8A on both bands (33), OA4SS (10), OF9L (15), 6W1RW (35), 3X5A (35), LT1F (13), HC8N on both bands (10), several Hawaiians (31), and lots of Caribbeans and even a few North Americans. With no sunspots, 15 was light and thin, so it was cool to work thousands of miles with those three little 2n7000's. I used a pair of fullwave loops cut for 20M on 15 and 20; yes, I have a tuner. The wires here are at 35 feet up.

Of course I tried to work numerous stations that never knew I was there. The band conditions were so light (long) that it was hard to hear stations calling the DX - so they sounded in the clear when there were lots of people calling. I could hear the QRO guys on scatter, though, because the BEE's receiver is excellent. You can beat Steve's MDS specs if you try.

The rig will do a lot af amazing things if you let it. It is a like a BEE the way it works.

More fun ahead...

I've been disappointed with the 9v Lithium disposable batteries for transmitting. Their main design goal appears to be shelf life, so they last a long time in low-current applications. Google found a datasheet here:
http://www.ultralifebatteries.com/documents/techsheets/UBI-5180_U9VLX.pdf
that says "max discharge 120 mA continuous, pulse capability up to 400 mA, depending"
There's also a graph of voltage vs elapsed amp-hours for a 60-ohm load. The battery immediately drops to about 7.7 volts, and drops below 7 volts before 0.8 Ah.

For lightweight disposable batteries that work in the cold, try lithium AAA's -- they do support high current applications.

Glad to hear all is well (with both you and the new rig).

I have been busy as a one-legged man in a kicking contest trying to clear the path for a planned semi-retirement January 31. Consequently, I have been all tied up in knots and unable to do much hamming or building. But the end is in sight.

The local SMT Elmers are hyping the Cash Olson hot air technique, so that is likely the route I will ultimately go with the '3B. Just got new glasses, so I'm hopefull I'll be able to keep track of all the components.

Meanwhile, the '3A continues to perform very well. I get a lot of pleasure out of that little rig. Thanks again for your help with it.

All the best for the holidays and New Year.

2286. ATS3B "Check and Calibration" Question

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-26 22:09:47 UTC
From: mikee30h
Topic: 2286 Message: 2286

I'm moving along on the 3B build. It was sweet to hear the "8" in the headphones after chasing down a couple soldering errors.

Now, however, In doing the check and calibration steps called for in the instructions (just after the filter board assembly), I found that when I put a voltmeter between ground and the
drain on Q4, the voltage is not slowly decaying to zero after I stop sending a series of "dahs".
The instructions indicate that the voltage should go slowly to zero.

So, I guess there is a problem in the keying circuit. Suggestions on where to look for the problem?

Thanks.

Mike NR7F

Hi
When I came to test mine I had same problem. However when I did the test on Q6 the test worked. I assumed thre was a typeo error in the information that Q4 should have read Q6. I have now completed the rig and it works superbly, with no problem with the CW at all.

Jim,

The test for the drain voltage, which should decay when you stop keying, is done on Q6, the mosfet with "2955" on it. This is a fairly large component with a large tab. The part is Q6 on the board designator, and it's Q6 on the REVISED drawing found in the FILES section here.

The part is Q5 on the earlier drawing with errors in the designators. The text in the manual refers to Q4, which was correct for the "A" version.

You really want to check the drain of Q6!

Thanks, Jim and Carey, for the info. I suspected an error in the instructions since it referred to a "large tab" on Q4; the tab on Q4 is definitely not large. I almost always assume the problem is me, not the instructions (because it IS usually ME that is causing the problem!)

The test works perfect on Q6, so it's in good shape so far.

Onward to the next test.

2291. Drawing Error - ATS-3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-27 00:58:50 UTC
From: radio_kx0r
Topic: 2291 Message: 2291

All,

Since we're on the subject of designators, I found a really minor error on the new drawing for the receiver section. It affects the connections shown on the drawing, but there's no functional issue.

On the board, the bottom end of R2 is connected to pin 3 of U3a, the first LM4808 audio amp. Likewise, the bottom end of R4 is actually connected to pin 2 of U3a. These push-pull audio connections are reversed on the revised drawing. The number designators are OK, if you follow them from U2 down.

The drawing for the ATS-3A has the same reversal error.

This doesn't affect alignment or troubleshooting, unless you're working on those particular audio lines.

Steve,

I updated my 3B firmware using the 220 ohm resistors in the interface cable and using the latest IAR software (slac050q.zip). 80m DFE and XIT now work as advertised. Looks like we still have to be in straight key mode to get the firmware version, but that is not important. Thanks for the updated firmware file.

From: mpupeza
Topic: 2297 Message: 2297

DON'T USE AN STAINLESS STEEL 'KURLY KATE' TYPE SCOURING PAD TO CLEAN YOUR TIP!
My soldering iron tip went bad while I was halfway through the page 13 resistor installation of my 3B.
It started to not wet properly with little spots of unwettable areas on the tip, making it hard to get the proper flow of solder to my resistors - especially those little 603s!
I quit for the day, and ordered some ST-7 Weller conical tips from Newark! (They came in 3 days!)
I wondered WHY did this tip fail, after building many little kits? I use a WLC-100 cheapy Weller, which I control carefully with the adjustment. I haven't had this happen before, and I have made a bunch of SMD , and other, kits!
I then realized that, about a year ago, I stopped using a wet sponge and went to a recommendation, from a QRP group.
I placed a stainless steel 'Kurly Kate' type of scrubbing scouring pad into a small can and was using that! No wetting down with water!
It worked GREAT! I just poked the tip into the pad and turned or worked it around.
BUT, I now realize that it's been slowly taking the plating off the soldering tip!
With the new tips I've gone back to a wet sponge!
Messy, but I'm now confident that it'll keep the tip better.
I hope this helps.

Hey Mike and the gang;

Your right... the correct 'Kurly Kate' is the brass-looking one.
(Copper/brass colored.) If you cannot find it at the local store, check
the electronic parts emporiums, although it will not be sold under the
"Kurly Kate".

I used one of these on my bench. My tips did NOT fail over a two plus year
period, using the iron several times a day, at least 5 days a week, in
daily bench repairs of electronics.

From: Paul J. Beckmann
Topic: 2297 Message: 2299

Here's another thought:

I used a wet sponge for decades until someone suggested placing a doubled-over hand towel on my thigh and wiping the tip of iron there every now and then. Yes, it is dry. No it doesn't burn the towel or your thigh unless you lay it down there and start looking for a lost 603! (You're not using a 60W iron, right?) Try different cloths until you find one that doesn't leave little strands of fuzz on the tip and you'll be a happy camper!

The major issues I have with the wet sponge technique are a) it drops the tip temperature dramatically and b) it thermally stresses the plating and may result in premature plating failure.

2300. KC2 and ATS3A

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-30 02:47:01 UTC
From: kc0pet
Topic: 2300 Message: 2300

Has anyone used a Wilderness KC2 keyer/counter with the ATS3 or know if it will work? I have an "A" and am thinking about enhancing it with a freq. counter. The KC2 is about the smallest kit I can find. I am open to other suggestions as well. I would like something that will fit in a 'toids tin. I plan to mount two tins back to back with the ATS3A in one and the counter and some larger push buttons in the other.

2301. Nor'Easter SW kit question

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-11-30 12:42:13 UTC
From: John Shadle
Topic: 2301 Message: 2301

I know this is the ATS list, but bear with me...

I am soon to be in the possession of one of Steve's/NorCal's Nor'Easter SW kits. It is similar to the ATS rigs, I believe, but only has RX capabilities.

In preparing for its arrival I have done a little searching on the web for any "issues" I may face as I assemble and align it. I found that the Atmel CPU needs to be reprogrammed in order to fix the 10KHz offset problem. Read here for more:

http://www.io.com/~n5fc/noreaster.html

"There's one other little bugaboo in the works... but it's only a minor inconvenience, and not a functional one. The microprocessor firmware, as delivered, displays the frequency as 10 KHz LOWER than the actual frequency selected. That is to say, if you want to tune to WWV at 10.000 MHz, the display will read 9.990 MHz. The designer, KD1JV, has indicated he is willing to reprogram the uP, for those that find this bug unsettling."

I contacted Steve, but haven't heard back if he can still do this. Maybe my email didn't get through the first time or he is out of town/busy. Can anyone help me out here or offer some advice on how I can do this myself?

Thanks.
-john W4PAH

>

John,

I hate when really old kits come back to haunt me :-)

The NorCal Nor'easter is an AM only SWBC receiver with PLL VFO which tunes from about 5 to 16 MHz in 5 kHz steps.

It is quite possible the original owner had the chip reprogrammed. Unfortunetly, there is no way to tell until you build it (unless its already built).

The only way to reprogram that chip is with a Atmel programmer. To my knowlage, there aren't any simple programmers you can build yourself. You also have to build something to hold the chip and connect leads to it, as its a SMT chip. If its already on the board, wires have to be tacked onto it, as it doesn't have programmer pins built onto the board. Finally, you need to have the program to load into it.

I should have the program around here someplace. That project was done in the old DOS days. I guess I could still reprogram the CPU, but it might take me awhile to get around to spend the hour or two it will take to find and set up everything.

2303. ATS-3B Power Output

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-02 00:41:39 UTC
From: mikee30h
Topic: 1984 Message: 2303

I finally got to the last check on the 3B build, and although the radio works fine, power output on 40M seems low. I have only built and checked the 40M board at this point.

I only get about 1.5W with a 9v battery, and then about 3W with the 11.1v LiPo. With a full 12V I get a bit under 4W out. I have rechecked all windings and cap values. Scrunching or spreading out the windings has no significant effect. I used two different, accurate wattmeters and get the same output. Although I do not care about squeezing the last bit of power out, and I don't really want to modify the filter boards, these readings definitely seem to be on the low side by at least half a watt or so. Can anyone suggest something else to check? Has anyone else gotten similar results?

Thanks for any thoughts on this. Mike--NR7F

If your 9V battery is a rectangular battery then I
would not trust it. Get a more robust 9V source and
see what it gives you. If your still "low" then short
of modifying the filter board (either turns on the
inductors, cap values or both) there is probably not
much else to do.

Everyone of my filter boards (3, 3A, and 3B) are
modified from stock. I don't change them for max power
but rather uniform power and I shoot for 2.5 watts
with a 9V source. This usually gives me 4+ watts with
a 3 cell lipo which is plenty for me.

Well, after scrunching both windings the power came up a bit. Once I glued them in place it seemed like the power came up even a little more. It's just under 2W with the 9V, 3.5W with the 11V, and a solid 4.5 with 12V. This just about in line with my 3A, so that's fine for me. I think initially I just hadn't scrunched the windings enough, and them I was only doing one or the other. In this case, it's works best with both of them scrunched up.

2306. Why not upside down Filter Trimmers!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-02 16:00:47 UTC
From: mpupeza
Topic: 2306 Message: 2306

Steve, et al;
Why not mount the Filter Board Timmers upside down, folding back the existing tabs and using short lengths of solid wire to the holes?
I'm at the stage of making the Filter Boards and can't see any problem with doing that - thus allowing changes of adjustment through the holes already made for the older bottom adjust trimmers.
I may make one to try myself - it's easy enough to change back!
My preliminary tests show the newly assembled main board to be 'alive', so I am pleased.
Now to make the box, some filter boards and try it out!
I have been logging my assembly times, and will let the group know the times I needed for the various stages in assembly - when I'm finished!
What do you think of the idea? It would allow future adjustments if the cores had to be played with?

If you had to scrunch up both windings, adding one turn to each core will likely bring the power up to where it should be. Is it possible you happened to wind them one turn short? (though most people forget to count the first turn and end up with one to many)

Mike,

When I brought up 40M on my ATS-3A and also my ATS-3B, I saw about the same power levels you stated.

I posted details on how to optimize ATS-3B filter boards here. It's a WORD file in the FILES section. Please also look at my other WORD file listing the power output and currents I ended up with for all the bands.

On 40M I needed to increase C2F by adding 150 pf in parallel with the existing 680 pf cap. I found the same issue with the 40M module on my ATS-3A - power output really IS low on 40M. The coil adjustments are more reasonable after the increase to C2F. Adding to C2F is easier than rewinding a toroid, which is another reasonable option.

You probably can get 2.9W @ 9V and 5W @ 12V on 40M just by adding capacitance to C2F and re-adjusting your toroid windings.

Try tacking 50 or 100 pf across C2F, and re-adjust the windings, just to see if that takes you toward where you want to go.

Please read both of my writeups if you want to optimize all your modules.

The finals in this rig are getting strong gate drive on all bands. If the power is low, it's probably because the filters aren't quite matching the available output to the load. Be reasonable, and don't get greedy, if you make adjustments; monitor your current.

Efficiency is higher on the lower frequencies, so if you want to be conservative, optimize the low bands 80, 40, and 30M; and settle for a little less output on the higher three bands - like 2.5W @ 9V and 4.5W @ 12V.

Thanks for the comments everyone. I'm always so paranoid about putting the wrong number of windings on toroids that I recheck them a ridiculous number of times, and I've got the correct number of turns on there. It's the one mistake I haven't made in kit building...yet...and I've made some doosies.

Changing the number of windings, or the capacitance as Carey suggested would have probably been a nice option. It's something that I'll keep in mind for the other boards.

In any case, I'm quite happy with the output I have now. I don't really feel like I need that last half watt. My 3A has worked fine with those power levels, so that's sort of been my target.

I have tried several direct emails to Steve, but possible I am in a spam filter? I just opened the package my QBSA came in March 30, 2007 (I know, I got started late, but wanted to finish the ATS3B). Anyway, I am missing the CIRCUIT BOARDS. I checked throughly, in the CD envelope, etc. No circuit boards. A missing capacitor or resistor, or even IC I could handle, but need the circuit boards pretty much ;-)

I guess I'm offically sold out now. Had 2 left, but a check is in the mail for one and I'll have to give John the board for the last remaining one. As far as I know, I have no extra boards and everything came out even, so don't know what might have become of yours John. Oh, and this is the first I heard of the problem. I don't check the spam filter, as they get trapped by my ISP and have to get on line to do that. With dial up and pay-per-minute phone line (yeah, I'm the last one in the world to have such a thing, but on the average its cheaper, as it is in a buisness name) I try not to spend much time on line. Emails are quick.

2316. Starting to build my ATS-3B - couple simple questions

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-03 05:01:22 UTC
From: Jack B.
Topic: 2316 Message: 2316

1. Is it safe to assume the coils are all wound clockwise?

2. Are the link windings for LF3 on the 80m filter board wound with
the #32 wire?

That's all.

I did all the RF1 SMT resistors in one fell swoop using the hot air
method. I had decided to ramp my way into this particular project by
starting with the filter boards.

This is following on the great success I had using the SMT Hot Air
Method to assemble a NorCal Tuner Upper for 30m (see:
http://www.k6jeb.com/2007/11/30/using-the-hot-air-method-to-assemble-a-30m-norcal-tuner-upper-smt-kit-november-30th-2007/
).

Hints and Kinks:
If you don't want to worry about whether you wound the right number of
turns on a toroid (but you didn't count as you wound) and you don't
have access to enough magnification, just use your scanner (the one
under all the QRP Journals and boxes of through-hole parts) and use
any decent graphic viewer (FastStone Image Viewer is a great one and
it's free) to zoom in and save the magnifying glass for other things.

72/73
Jack, K6JEB

PS - I started building this rig in hopes of having something small
enough to take with on my travels next year (India is the current plan).

Jack:

I wound my coils in the counter-clockwise direction away from my thumb holding the core. But I am right-handed, a left-handed person might go the opposite direction. I doubt that it really makes any difference or else Steve would have stated something in the directions.

On the 80m LF3 I used #32 wire for both the main and link windings. Even then it was tough to get all the turns on.

Like you I started my 3B by building the band modules. I figured if I did them last I would be in too much a rush to get them done and increase the chances of making a mistake. I hand soldered my 3B though. Good idea on counting the windings using a scanner.

Off topic, I think I heard you on 20m PSK31 recently, but you were quite weak as we are pretty close (Sunnyvale), so I did not call.

Have fun building the kit, I sure did!

Hi Jim and Other ATS-3 folks,
Thank you so much for the quick response. I'm done winding the other two toroids and will now finish the LF3 link windings with the #32 wire.

I have a goal to to one of these filters per night until I have them done. This will be my second, the 20m being the first.

This Yahoo Group (or group of yahoos hi hi) has been an immense source of inspiration and information on the ATS-3(A and B). Thanks!

Since my wife and I are selling our home (hopefully to get a larger antenna garden) I'm down to just my Butternut HF9V up on the roof so I imagine that plus the ridge between you and I kept the signals pretty far down. But with all the great stations down your way, that ridge has probably saved my front end on several occasions hi hi!

Hoping to do some HF Pack PSK eventually with my ATS-3's.

72/73!

Also, looking at the remainder of the CT trimmers (I have two brown ones mounted on the 20m filter board) I have eight green ones and two brown ones. The green CT trimmers have no markings to differentiate them. Besides visions of a Wouff Hong coming down hard on my hands typing this, I'm also getting a very distinct image of me pulling out my Multimeter and measuring these components for capacitance and that would be just as good a method of figuring out which trimmers go on which board.

One problem, I'm not seeing the values for each of the boards/bands. Can someone point me in the right direction? As I said before, I already have the 20m board built (of course) and was on homestrech with the 80m board when I realized I could tell which of these to use since there are no brown/green markings. Just a green or brown casing.

:)

Glad I finally got through the spam filters. I just opened the package the other day. I put the contents in the large tray I use for SMD building, and absolutely sure there were no circuit boards.

John

2321. Time to build ATS-IIIB - my way!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-03 16:49:29 UTC
From: mpupeza
Topic: 2321 Message: 2321

Hi;
OK, Yippee again!
My ATS-3B is alive and working well on 40M so I thought that I'd
share my building times, for those budding future builders.
I used a coathanger doofus and hand soldering, and am pleased with
the results. I used +2.00 reading glasses and an Optovisor Number 5!
Obviously, my times will NOT be typical for all builders, as, though
I am skilled, I try to be precise and I am, maybe, slower than most!
Here we go!

Page 15 Resistors back side 100 Min 2 sessions
Page 16 Resistors Front 55 Min 1 session
Page 17 Capacitors Back 95 Min 2 sessions
Front 10 Min
Page 19 Active Devices 90 Min 2 sessions
Page 20 Thru-holes 105 Min 2 sessions
Page 21 Filter Modules 360 Min 6 sessions
Pages 23/24 Tesing/Calibration 30 Min 1 session
Page 25 Altoids Box mounting 180 Min 3 sessions

So, my worst case scenario, is 19 sessions of less than an hour each.
I usually did about 3 sessions per day. 2 in the morning and one
after lunch! Obviously, I am retired, and a senior!
While I still have 5 Filter Modules to go - I did the rest in about
one week.
A fun project, and I had NO issues after completion.
I hope all goes as well with others!

Mike,
Congratulations on your progress. You will find the Bee as much fun to operate as it was to build.

You have made a very important point that I hope does not go un-noticed.

How fast you build is no where near as important as How Well you build.

72,
Ran

2323. Question about the CT Trimmers on the filter boards for the ATS-3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-03 20:49:57 UTC
From: Jack B.
Topic: 2323 Message: 2323

Looking at the remainder of the CT trimmers (I have two brown ones mounted on the 20m filter board) I have eight green ones and two brown ones. The green CT trimmers have no markings to differentiate them. Besides visions of a Wouff Hong coming down hard on my hands typing this, I'm also getting a very distinct image of me pulling out my Multimeter and measuring these components for capacitance and that would be just as good a method of figuring out which trimmers go on which board.

One problem, I'm not seeing the values for each of the boards/bands. Can someone point me in the right direction? As I said before, I already have the 20m board built (of course) and was on homestrech with the 80m board when I realized I could tell which of these to use since there are no brown/green markings. Just a green or brown casing.

:)

72/73,
Jack, K6JEB

From: Michael Harnage
Topic: 2323 Message: 2324

Jack,

I hope that Steve chimes in here for ya, but based on
the past and how I think it may work I think you are
going to have to pull the brown trimmers from the 20m
board. The brown trimmers are probably for 80 amd 40
and the green the rest. OR the brown are for 15 and 17
and the green the rest. Either way I think 20m is
going to be green.

You could always measure them and match them properly
so that the rx filter is tuned correctly. It is a
simple double tuned design and the LC calculations are
straightforward and standard.

If Steve doesn't chime in soon, answer back with
measure values and we can try to help you sort it out.

By the way, here are the values for the original
trimmers on the first batch of 3B's

>BROWN/RED 70p
>BROWN/GREEN 50p
>BROWN 40p

Jack,

I hope your using the instructions on the CD which came with the kit. You have a second run kit and use different trimmers and hence different instructions than those used for the first run kits. The manual which is in the files section is for the first run kits, not the second.

All the brown trimmers are of one value (70p) and all the green are of another (30P) The brown trimmers are used on the 80 and 40 meter board and the greens on 30 and higher boards. This is all explained on page 21 and 22 of the run2 manual.

The reason for this change is that I had already bought all of the type of trimmers used in the 100 kits which were available in the US. To get more would have ment a minimum order for like 2500 pieces and 10 had week lead time. So, I had to use something else which was available.

Thanks Steve,
That's exactly right. No worries, I only need to unsolder the two
brown trimmers from the finished 20m board. I've gotten into a groove
with one board per night (that includes the toroid winding) and still
be able to hang out with the wife and even watch a movie.

I had indeed just downloaded the manual from the web instead of using
the file on the included CDROM. Good head's up!

72/73!

LOL home brewing.:-) Steve had mentioned something
about a 3rd run after the holidays. I imagine if the
interested parties gang up on him with a pile of
emails, he might be cajoled into doing another run.;-)

Cripes, I would have thought that local hams would
have volunteered labor to help get the kits together
if they
get the privilege to buy one! :-)

Then again, if he thinks of something else to do with
the ATS, he might wait to issue a "new and improved"
model. I thought he posted that he thought he has
gone as far as he could with the ATS and if he wanted
to do some other things with the platform, it would
take more battery power. Don't hold me to this but
just my
recollection.

2331. power plug issues

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-04 17:24:09 UTC
From: John Shadle
Topic: 2331 Message: 2331

Whenever I apply power to the rig by plugging in the 9V battery I have to twist the plug in the jack and hold it in a certain position before the rig comes alive. If I let go of the plug and let it sit where it wants, there is no power. Clearly I can't hold the plug at an angle and operate the rig...

Anyone have suggestions as to the remedy to this problem?

Thanks.

--- In AT_Sprint@yahoogroups.com, John Shadle <shadle@...> wrote:

John,

Does this bad connection happen with the rig mounted in a box, or on the unmounted board?

If the rig is in a box, make sure that the power plug can go deep enough into the receptacle - the board has to be mounted at the very end of the box for the connectors to mate correctly. The two corners of the power-plug end the board must be rounded to make it possible to fit the board in correctly. The manual describes this.

If the poor connection happens on the unmounted board, it indicates a problem inside one of the power connectors - if the connector to the battery looks OK, it might be the receptacle on the board.

Be sure the power plug's inserted far enough.

Has anyone else seen this problem?

But, keep your eyes open on this reflector, and on QRP-L. There have
been several offers for the ATS-3b for sale, usually at the same price
that KD1JV was asking. Folks seem to find they don't have time or for
some other reason they decide NOT to build a kit, and put it up for sale.

You have to be observant, because the sales are generally completed very
quickly after one is listed.

I, for one, am content to wait until next summer - right now I have
several other things on the plate.

Indeed, I had planned on waiting until I got back from my AT hike in the spring to do more, but demand for these cute little radios just doesn't seem to want to go away. I guess thats a good thing, hi.

Well, I might start to order parts now and see if I can get a small batch or two out before the end of March.

Jess,

Much has been written on this group site about the various methods. I built the ATS-3A using a pointed soldering tip, and I built the ATS-3B using Cash Olson's solder paste, candle warmer plate, and a hot air tool (Hobby Lobby embossing tool). Both methods work fine. Neither is easy.

Search this site to read our previous posts. I'm not going to say all the stuff I said earlier, since it's easy to find. Search for "hot air", "Cash Olson", "candle warmer", "doofus", etc., and you'l find plenty to read from many of us.

No matter how you do it, it's a great radio once you get it all done!!

Why don't you practice on something first? Get a PWB out of
a junk piece of electronics (like an old ISA bus card) and
roast it, shake it, bake it and see where the boundaries are.
You'll be suprised at the amount of latitude there is with this
process. Even some True Curmudgeons I know (W9YA) can do it,
anyone can.

> The prospect of sodering all of those itty bitty parts a
> piece at a time does not thrill me either.

Once you get in the groove you can do several a minute.

> Has anyone tried the SMT/Solder method that also has done
> it the old manual way?

Last year I did a build for a customer that had 4800 parts,
all hand soldered (the layout precluded automated assembly).
Sure, you can do it. IIRC I spent about 6 hours putting my
ATS3A kit together (1 week of lunch hours).

> I am all for learning a new way to do things as long as
> there is not much risk of screwing it up

So take the risk out and practice on something else first.

Well, since the only "proprietary" part is the PCB, if
Steve would be willing he could order up a batch of those
to sell and let the builders source their own parts, saving
him the time/expense of kitting them up. Some enterprising
individuals could sell a kit of parts separately, and yet
others could offer to program up a batch of micro's. All the
doc's are done, partlists, firmware, etc, so it's just a matter
of gathering up the bits to make more.

When Steve comes out with a kit, one has to jump at it
or lose out. I was interested in the ATS3 and had to
wait awhile for the 3A. Jumped on board for the 3B
right away. Gotta be quick and can't procrastinate.

This was even worse before the ATS-xx days. Steve would do one run of kits and that was it. He might do a Mark II version but if mym memory serves me, he never did a second run of the same kit before the ATS rigs. Now, this may be due to more demand these days for the popular ATS rigs - it certainly isn't due to a jump in quality - all of his designs are really great !!

I very much plan on using the Cash Olsen method. I've already done a practice kit (a 30m NorCal Tuner Upper) and the results were so much better than the 20m Tuner Upper I built one component at a time that I would even venture to say I now PREFER SMT over through-hole because this method works so well.

Happily, American Ingenuity is alive and well and Cash's method is proof of this (as are the multitude of great sites Gil included below).

I dare you, no I *DOUBLE DOG DARE* you all to try Cash's Method as it really works well. Before this, I simply dreaded soldering SMT parts. I have the equipment, but it was still a bit frustrating to spend so much time working on such tiny stuff (I would have become a jeweler or a surgeon otherwise).

For my builds I set my electric skillet to just below 200 degrees which shortens the time I have to spend getting the paste to flow, but it lengthens the time to cool off.

It would be interesting to clock the different methods and error rates.

I've been exchanging notes on flickr with another Bee-Builder over here in JA1. He has posted some intriguing designs both in the photo section of this forum, and on Flickr (which I can't figure out why Yahoo hasn't merged--flickr is so robust for commenting and discussing photos of QRP projects).

In particular my eye was caught by this "BB Adapter". The excellent photos do tell a story, but could another of you who is familiar with what this is describe what you see in the photo: <http://ph.groups.yahoo.com/group/AT_Sprint/photos/view/8fbd?b=10&m=f&o=0> more fully? What is it, and why/how might I make my own?
Thanks to JN1GLB for excellent explanatory photos,
Jonathan
PS. If you're hip to the flickr thing, comment over there under the appropriate photo. <http://www.flickr.com/photos/21084785@N06/>

I had the same questions when I was faced with building mine, and did it by hand, since I had no experience with reflow methods and didnt want to experiment on a 190$ kit! It was actually fun to do the soldering by hand, but I think Im going to experiment with some junk board and an old toaster oven I have.... I need to find a decent thermometer that reads in the appropriate range...anyone found a good source?

2358. Flickr ATS group formed

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-05 02:22:40 UTC
From: kc7fys
Topic: 2358 Message: 2358

This Yahoo group is completely sufficient for exchanging ideas and tweaks on the ATS lineup of QRP rigs. I have, on occasion, wished I could comment on photos or ask, "What's that thing you soldered on there, buddy?" --when looking at your photos in the 'photo' section of this group.
For this reason, I have taken the liberty of instituting "ATS-QRP" on Flickr. For those of you who are familiar with Flickr and use it, there is a very robust show-and-tell exchange of ideas that is possible when notation and commenting on photos occurs.
The URL of this group is: <http://www.flickr.com/groups/ats_qrp/> if you want to sail on in and see what's there. If you have ATS photos on flickr, you can add them, browse others, comment, cajole, argue, whatever--while looking at the equipment in question.
Please disregard this notice if you're rolling your eyes, saying, "Oh, geez, not another offshoot...." This YahooGroup forum is completely adequate for what it is, and I mean no distraction whatsoever from the present conversation here.
Thanks,
Jonathan KC7FYS/7J1AWL

2360. Fun radio

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-05 03:53:02 UTC
From: Bill
Topic: 2360 Message: 2360

A friend of mine and I always talk about which radios we have owned that were fun. Some radios just have fun built in. The Index Labs QRP+ was a fun radio. Something about the few buttons, big tuning knob and shape of it just made it fun to operate.

The ATS3B is a fun radio. The simplicity, the 4 buttons, the one digit display, and you get to build it too. Add to that the great receiver and all the features you really need in a small package.

I have just been amazed with this radio since I finished it. The other kd1jv design I added on also helps the fun of my configuration. I combined the radio with the alt tuner, the original style with the jumpers, in one tin. There are photos of it in the photo section of the group site under my call sign.

Hey Jonathan,

I know what it's like to look at ordering one toroid plus 6 to 8 dollars for shipping and handling. I guess we all do.

I have a few and will gladly mail one to you.

Are you in the United States or Japan or something? Where is Akihabara anyway? Oh I see it is Japan from wikipedia.

Ok give me your address.

This is just the core by the way. You have wire?

I myself am looking for a few toroid cores. (At the risk of turning the forum into a toroid exchange group ...) If anyone has a T130-6 and/or T130-2, I could use one of each. I'll pay you the few dollars plus what ever envelope shipping is.

As much of a hassle as it was, I have to say my HeathKit HW-101 I had as a Novice comes to mind as a fun radio. Memories of setting it up in a tent in the back yard for contests as a teenager. Doing mods on the board to help improve received audio, as well as dropping hot lead into the knob to give it a weighted feeling.

I also have fond memories of building a Tuna Tin II completely from scratch (I scrounged or made all the parts, no kit then). I think seeing the look on my High School Electronics Teacher's face when I got a reply back to a CQ (and the resulting A I received) were not only fun, but inspiring.

Conversely, I would say I have also had experiences with no-fun radios. One that comes to mind is the PRC-77 I would often get stuck carrying while I was in the army infantry. But that's another story. :)

Of late, hands-down the Fun Radio award goes to my current construction of the ATS-3B. As many of you probably know, I've been doing one band filter board per even (mostly it's just winding three toroids and mounting a few through-hole components, I mounted the SMT component on the five boards (there is no resistor for the 80m board) at once with Cash Olsen's hot air method (it's not just painless, it's fun!).

In fact, last night after I did my nightly ATS-3B filter board build, I rather quickly mounted and soldered SMT parts to both sides of an FCC-2 just for fun. So it's not a radio (yet) but it was fun!

My first rig was a second-hand HW-16 that I had a lot of fun with for about a year as a Novice/General. Then during a semester break from college back in Jan '72 I built an HW-101 and proceeded to operated it for over 20 years before selling it off.

Say Jack, are you planning to use your FCC-1/FCC-2 with your 3B?? I would be interested in hearing how it works out.

2367. psk31 problem

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-06 04:20:38 UTC
From: Bill
Topic: 2367 Message: 2367

The rig started out working fine but then
would not stop transmitting after sending psk.
Even using the transmit button or sending
$rx. I tried even editing a macro so that all
it was sendng was the switch to receive macro.
Sending seems to work fine every time, but I
have to pull the power to kill the transmit.

Any ideas from anyone?

thanks,
Bill, ni5x.

2368. qfox] 40 Meter Fox Hunt - Thursday December 6, Local

Topic: 2368 Message: 2368

Hello Hunter Hounds,I will be one of your Foxes for this week's 40M FOXhunt. I've gotten my antennas repaired from the 70 + mph winds of the last week or so.and... I'll be listening for you as I poke my furry tail up... somewhere in the 40 acre wood, between the .030 and .050 trees.I may start out simplex, so listen for the ""up" or not then listen for the hounds too..However, IF I can hear more than just a couple hounds at a time, be ready for "up" to occur.The hunt starts at 0200z on Friday, December 7th. That is Thursdayevening, local.I'm located in the Wild West, where the pavement ends, and the West begins,Or.. as some have said of late, where the winds never stops.And I am doing my best to slow down the wind with 2 360 foot long phased arrays,and 2 verticals, and a simple dipole. One of them will hear you... I hope.Come early and stay late... we'll have a ton of fun, Chasing through the sage.Handing out pelts to every waggin tail to be heard.Y'all come, so ya kin hear.--... ...--Dale - WC7S in Wy_____Connect and share in new ways with Windows Live.http://www.windowslive.com/connect.html?ocid=TXT_TAGLM_Wave2_newways_112007

>The rig started out working fine but then
>would not stop transmitting after sending psk.
>Even using the transmit button or sending
>$rx. I tried even editing a macro so that all

Bill,

I've been in contact with Vojtech the last few days working on this very same issue. The problem apparently is caused by a voltage spike generated by the sound card when the output is turned off and this confuses the decoder in the ATS3B. I had no such issue running with a Pocket PC and only just the other day tried using the desktop version.

Here is the fix Vojtech just sent me. I tried it and it works. Now the rig goes back to receive with no problem and the "test" button in the setup menu works, which also wasn't working before.

****

Please stop PocketDigi, start regedit, go to
[HKEY_CURRENT_USER\Software\OK1IAK\PocketDigi\TrxCtrl]
Now you will see following values:
"Type"=dword:00000004
"COM"=dword:00000003
"Ats3FreqOffset"=dword:00002530
"Ats3Preamble"=dword:000001f4
"Ats3Postamble"=dword:00000014

COM and Ats3FreqOffset will probably have different values from this list.

Now copy the value from Ats3Preamble to Ats3Postamble to make it 63msec long.
Launch PocketDigi and try whether the Test button works.
If not, stop PocketDigi, start regedit, make the postamble 2x longer, start PocketDigi and try it agan.

****

My rig started working with the Ats3Postamble set to 01f4.

It took me a minute to figure out how to edit the value. Double click on Ats3Postamble in the list and a value edit dialog window will open.

Open regedit by going to >START> RUN and type in regedit. You must be an administrator to edit this.

Vojtech says he will have a new desktop version of Pocketdigi out soon, where the pre and postamble values can be edited direct from the program and has a few new features like sound card clock calibration.

I tried running Pocketdigi on an old Win98 PC and the ATS-3B would not respond at all to it. I'll try playing with the pre and postamble times and see if that will make it work.

Steve,
Thanks for the quick reply and fix on this.
Just one more reason to like this radio and
appreciate your work. I will have to wait till
I get home this evening to try it out.

Did you happen to look at the photos under my call
sign for this group? I used another of your designs
to pair up the the ATS3B, so far seems to work very
well and easier to carry. Not exactly low on weight
but I am too old for backpacking anymore anyway. :).

Bill, ni5x.

I got my old Gateway Win98 PC to work with Pocketdigi/ATS-3B by reducing the preamble time quite a bit. From 1f4 to e4. So, it seems tweaking the preamble and postable times constants to match the characteristics of the particular sound card being used is important to getting it to work.

I'm glad it now works with the Gateway, as it is located next to my radios and will much more convent to use than the Pocket PC.

Hi Jim,
I read with interest the piece on using the FCC-1 with the ATS-3(x) but initially I plan to use them separate. I may however make the connection between them modular. The FCC-1 is a bit large for an Altoids tin, but it would be cool to have some sort of 'stacking' modularity.

I'm also thinking about building my ATS-3A in a more 'portable-fixed' configuration, which would definitely include the FCC-1. I'm still trying to figure out how I would use the FCC-2 with the ATS-3. I don't know that I could use it to key RTTY and there's already a VFO in the ATS-3. But I love the idea of the FCC-1+ATS-3!

One thing that used to be a pastime as a teenager was scavenging the many tv's on the curb (seemed like every week another would appear somewhere in our neighborhood in the early 80's). We'd take the vacuum tubes to the local shop with a tube tester and then look up the substitutions. I seem to recall a few tubes in the HW-101 were easily substituted by others found in virtually every TV at that time.

Also it was a blast unwinding the CRT coils from one end of the neighborhood park to the other several times. At the time I thought that if you just got enough wire in the air, you could work the world. I was mostly correct. :)

I will add that lately, I've been having a blast with my FT-857D which is small enough for HF Packing while having all the features of larger and more expensive rigs. Some folks are confused/turned-off my the menu system. But with few exceptions, most of them are 'set it and forget it' adjustments. As most QRPers are aware, you really don't need a lot of bells and whistles to have fun. OK, maybe sometimes an extra bell or whistle helps . . . I just got my 500hz CW and 2300hz SSB W4RT Collins filters for my FT-857D yesterday and talk about a HUGE improvement! My IF shift is actually useful now! DSP now ***REALLY*** cuts through.

Blah blah blah

Finally, tonight I finish the sixth band filter board for my ATS-3B. It's been quite easy going. My plan is to mount the SMT components on the main board over the weekend and then finish up at least the build phase over next week. So far I've spent less than six hours (that includes breaks and taking photos along the way) which is mostly winding toroids.

If you put off building your ATS-3 because you dreaded winding toroids or mounting SMT parts; take my word for it, you'll be glad you started

because your gumption will increase with each step you complete.

72/73!
Jack, K6JEB
www.k6jeb.com

PS - I put up some more photos of building the filter boards on my web site.

2379. Hot Air SMT Soldering on Double-Sided Circuits Boards your thoughts?

Yahoo group: AT_Sprint (2002 — 2008)

I'm guessing it would be preferable to re-heat components as little as possible. So as I look at the main board of the ATS-3B, I wonder which side to do first? I'm leaning toward doing the Front side (the side with the LED readout) since fewer parts would later sit against the pre-warming surface when I do the Back side.

For those who have used Cash Olsen's method, how did you go about it? Front side first? Back side first?

Would having more components pressing against the pre-warming surface (if you used a pre-warming at all) actually HELP because of increased contact?

Finally did you do the active components last? First?

--- In AT_Sprint@yahoogroups.com, "Jack B." <k6jeb@...> wrote:

Jack,

I used the Cash Olson method, and here are my suggestions:

1) Place and reflow your parts on the side with the fewer number of parts first.

2) Use a preheat device like a hot plate, candle warmer, or skillet. It will be touching the side of the board with no parts when you solder the other side. Temperature of the plate should be high enough to make water drops boil and just dance - no hotter. You risk board damage if you use too high a temperature for preheat. No preheat requires hotter air and makes the thermal profile worse.

3) In previous posts several of us have described our setups in detail. I have photos of my candle warmer preheater with heat spreader posted in the PHOTOS section on this site. I wrote this up in detail. Please search our previous posts, and you'll find a lot of discussion of just what you're asking about.

4) Solder the LED readout after all the other parts are installed. It's easy to hand-solder, and it's best done at the end of the game.

5) You don't want your already-soldered components to touch the prewarming surface directly. It's easy to support the board with coins or washers at the corners, so the parts don't quite touch. Most of the heat from the surface rises through the board anyhow.

6) If you use the hot air tool correctly on the upper side of the board, the parts on the reverse side won't reflow. One reason you don't want those parts touching anything is that if they DO reflow, you don't want any force on them that would cause them to shift. Surface tension of the melted solder will hold parts in position, even upside down, as long as nothing touches them. If your heat is OK on both sides, melting of the underside won't happen.

7) For each side, I placed most of the parts with solder paste, and then reflowed that side with hot air. On the side with the most parts, it gets tough because there are so many parts; it's easy to slip and mess up a couple. It isn't too bad if you're careful. You should complete each cycle of placing parts and reflowing them. It isn't a good idea to leave the parts sitting in paste for hours - it dries out -you need to get them melted soon after they're placed. So allow enough time to place your parts and reflow them. Others have

suggested soldering the parts in groups, which means some go through more than one heat cycle. If you do it that way, I'd suggest starting with the passive parts, resistors and capacitors, so that the IC's are in the last wave. The IC's should go through just one heat cycle, if possible. Be sure you get all your IC's oriented right - triple check them and READ THE MANUAL - study Steve's pictures.

8) Some parts should NOT be soldered with hot air. I suggest you solder all connectors, the socket strip, all electrolytic caps, trimmer CT1, L3, the display, all crystals, D3, the pushbuttons, the clock oscillator, and the three 2N7000 mosfets by hand, per the manual. These all go on after the SMT parts are done.

9) Stick with the manual and the order for the parts as much as possible - this helps avoid mixups. I think the color drawings are very helpful.

10) I would ignore people who suggest toaster ovens and the like. While they may melt solder, the 1500 watt elements and high thermal mass are not what we want for the thermal profiles we're trying to match. Toaster ovens create a lot of infrared energy, which may overheat some black parts, but not the solder, unlike the hot air. Using a toaster oven is like using a sledge hammer to crack a peanut. Even if you use a thermometer in one, you may be misled by the concentration of infrared energy.

11) The beauty of the hot air tool (320W embossing tool) is that you can watch what's happening - you see the solder paste changing and then melting - you know when you're hot enough - you have immediate visual feedback on what you're doing - and you can avoid getting things too hot before massive damage occurs. Don't get the hot air tool too close or get in a hurry - spend at least a 2 or 3 minutes bringing the temperature of the parts up slowly before getting in closer for the peak of the melt cycle. You can paint the hot air over the board so you go slowly from one zone to the next. You won't have it all molten at one time with this tool.

The complete soldering of all parts on the denser side takes several minutes after you begin with the hot air. Gradually raise the tool and keep painting the air once you're sure you've reflowed all parts - you want to have a gradual drop in temperature as part of that thermal profile.

12) My candle warmer with 1/4" thick aluminum heat spreader has so much thermal mass that I chose to remove the board from the little hot plate a few minutes after I was finished with the hot air. Avoid using too long a duration of preheat and postheat. My candle warmer and spreader take so long to fully warm up, that I compromised and put the board on the preheat surface only after it had heated up. To avoid a thermal shock, I used spacers to lift the board at first; after a few minutes, I removed them and let the board sit on the

aluminum, which was probably at about 250 degrees F. After maybe 5 or 10 minutes of preheat I used the hot air for the reflow, etc.

13) This method works so well because you use your common sense and intuitive judgment. If you avoid thermal shocks and don't let the temperature rise too high, you'll end up with a nice job and the prospect of excellent long-term reliability.

14) The direct soldering method delivers thermal shock to many components, so it's not really a conservative approach.

15) It's helpful to look at the thermal profiles recommended for SMT parts on various data sheets - they're very similar these days, since most commercial board operations use automated equipment in a controlled process.

16) Many of today's parts are designed for no-lead solder processes, which means a higher temperature than what we need for our lead solder paste process here.

In my several decades of involvement with electronics, watching my ATS-3B board reflow stands out as an amazing moment. It's right up there with the first time I heard a regenerative detector function!

Have fun !

Excellent tome Carey. What if one can't get all the
parts placed in one sitting? Is it O.K. to put the
unit
in the fridge in a Tupperware container to await the
next session?

I'm going to try tackling this project first:

http://www.ramseyelectronics.com/cgi-bin/commerce.exe?preadd=action&key=MR6

I have a hotplate I'm going to stick a piece of flat
steel across and test the temp and of course find the
setting that just gets water to dance.

Some of the resistors in that transmitter are smaller
than the ones in the ATS3x kits.

Kurt,

Yeah, tome is right. I think your idea of putting the board on the fridge is fine, but..... Once is's loaded with parts there is some risk in handling it. I think if you plan how you're going to do this and handle it really gently, you might get away with putting it "on hold". I'd suggest putting it in something where it can't slide around.

Let us know how that works out.

From: ak3f
Topic: 2386 Message: 2386

i posted a jpg of the warm up profile of my 15 w walmart cup warmer in the photo section. it topped out at 290 F.

i thought that was a little too hot, so i laid a 1/4" thick disk of black anodized aluminum on top the warmer and tried again. with the aluminum disk it topped out at 235 F and took much longer to get there (35 minutes).

i think i will use it with the disk. the disk also raises up the hot surface so that the 3B board can lay flat on it without touching the white plastic edges of the warmer.

this warmer is 3.5" in diameter.

Mike,

Thanks for the curve and the photo. My candle warmer is similar, except that the aluminum is 1/4" thick. I got a larger, flatter surface, and much more even heat with the plate. I think this is a good concept.

The coffee pot warmer sounds like a good idea also, as long as the temperature is OK. Most of these appliances seem to be somewhat similar, since their purpose is to heat, not boil. I think it's a good idea to use a hear spreader, even though it slows the warmup, because some of these hot plates are thin, and there may be a hot spot. A hot spot might damage part of the board.

As I posted earlier, if you put a 140 VAC variac on the AC line, you can get some variation up and down from normal.

Sure!
I built the 3A and go tthe cup warmer from Wal-Mart which was too small to fit the board onto. I found that the warming plate on our coffee maker was the perfect size for the board. I placed the board on the warming plate and followed Cash Olsens instructions for warming the board. It worked perfectly! I am sure that your idea of another wider plate on top of the warming plate you ahve would also work but what I am getting at here is that I do not think that this is all that critical...
So I would not worry too much about what you use ..it will work and you will get a good result either way.

Hi Bill and Steve.

Thanks for reports on the preamble/postamble lengths. I will make them configurable in the software in the next release.

I understand clearly why prolonging the postamble works. But did you really need to shorten the preamble? Didn't it work with the old value?

Hi Vojtech,

I shortened the preamble because I wasn't getting any transmit,
but I was trying several things, I know, not the correct way to
troubleshoot, but I got it to work, so I included that in my report.

I also increased the transmit volume, that is more likely the solution
to my lack of transmit.

Bill, ni5x.

PS: thanks for the software, just what I have been looking for,
extremely portable psk.

was fine business to ae3dl in Pittsburgh
who gave me a 589 but my transmit and recieve
frequencies were off by bout 300 on the pocketdigi
display. I had the offset in the setup at 377hz.
I am in Mounds, Ok. south of Tulsa. not bad for 3 watts.

Just need to figure out the offset so I quit missing
the come backs.

Bill, ni5x.

Vojtech,

The rig would not respond at all to the sound card in the Gateway Win98 PC until I made the preamble quite a bit shorter. My slightly newer eMachines XP box took making the postamble longer to make the rig come out of transmit. I had no issues with the h/p iPDQ Pocket PC in making the rig work using the default values. Otherwise, we might have stumbled onto this problem earlier.

So, making both parameters adjustable is a good idea. Seems no two sound cards are alike in how they turn on and off.

Congradulations Bill!

Your offset should be about 600 Hz. The variable is exactly where your BFO timmer happens to be set. Mine ended up at 558 Hz, but is sounds like your will end up about 650 Hz.

2415. Announcing the birth of my new ATS-3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-11 00:45:52 UTC
From: Jack B.
Topic: 2415 Message: 2415

Firstly, thanks to all of you who provided excellent advice on building this with a hot air tool. The results paid off. That moment when I saw the digital read-out come on and I could hear the CW was one of my best amateur radio moments.

I brought the little radio to life yesterday (Sunday December 9th) and I have to say WOW! What a great little receiver! I put it on the same antenna as my 'big radios' and could easily tune in any station I could hear on the others.

I'm saving the joys of tweaking power output for later. I am getting 3 watts on 12VDC on 40m, 4 watts on 80m 30m and 17m. And nearly 5 watts on 20m and 15m. Alignment has been quite easy. I'm using MultiPSK for spectrum analysis of the audio. The signal sounds clean and well-formed.

This radio is so small yet full-featured, I really am starting to wonder if Steve got his via alien visitation (hi hi!). Really though, the components stood up just fine to heating and sometimes re-heating with a hot air embossing tool.

One small 'glitch' I'm running into is getting a nice rectangular hole so small on the tin. :) I'm wondering if there's a 'punch' that would work. So far I've just done the 'drill-a-hole and file like a mad-man' method but the results aren't as perfect as the holes I make on the drill-press.

Oh yes, and by the way, one typo in the assembly manual: the hole for the four retaining screws is NOT 7/16". :) You'll see that's a pretty obvious misprint when you get to that part. I don't have the hole size off-hand, but it's pretty small.

During the build process, I video-taped small segments. I'll try and get that up on my site ASAP (and for sure it's fine to re-use any of that here on the ATS-3 group if it rises to the quality already here).

So I'm going to head home and see if I can make a few QSOs on my new ATS-3B!!!

72/73,
Jack, K6JEB
www.k6jeb.com

PS - Using my computer scanner to take a high-res photo of the ciruit for close-up inspection was VERY helpful during this build. I was able to see bridged connections and even raised/unsoldered IC feet this way which I had missed when I did a once-over with a really good

magnifying glass.

PPS - So where do I find my ATS-3B serial number? hi hi (j/k)

2416. December NAQCC Sprint

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-11 02:25:22 UTC
From: Larry Makoski
Topic: 2416 Message: 2416

This Tuesday evening, the North American QRP CW Club will be holding its monthly sprint.

Here are the particulars:

Date and time:
Wednesday December 13th, 0130-0330 UTC
(Remember that's Tuesday evening here in the USA) That's 8:30 - 10:30 EST, 7:30 - 9:30 CST, 6:30 - 8:30 MST and 5:30 - 7:30 PST.

Bands - Frequencies:
80M - 3555-3565 kHz (Be courteous to FISTS operating on 3558 kHz)
40M - 7039-7050 kHz (Avoid W1AW on 7047.5 kHz).
20M - 14059-14065 kHz. General:
A particular station may be worked once on each band. Operate CW only. All licensed amateurs are invited to participate, but only those operating QRP (5 watts or less) are eligible for awards.

Call: CQ NA

Exchange:
RST - SPC (State Province or Country) - NAQCC Nr.
(non-Members substitute power level for NAQCC Nr., e.g. 5W, 1W, etc. Be sure to add the W.)

QSO Points:
QSO with a Member, 2 points.
QSO with a Non-member, 1 point.

Multipliers:
Each USA state
Each VE province
Each country except W/VE
All multipliers count only once in the contest.

Bonus:
If you use only a straight key for the entire sprint, multiply your score by 2.
If you use only a bug for the entire sprint, multiply your score by 1.5.
If you key with anything other than a straight key or bug, there is no bonus multiplier.

Categories:
SWA - simple wire antennas - for those using a simple wire antenna per NAQCC definition.
GAIN - gain antennas - for those using other than a simple wire antenna.

Special Award:
Our special award this month is a simple one. One certificate goes to the longest licensed ham and one to the most recently licensed. The year of your FIRST ham license is the determining factor. You need not have kept the license active continuously. You must also make at least 5 QSO's in the sprint to be considered for the SA.

Autologger SA info:
Eligible for the Special Award.......' box - Select Yes
Special Award info.......' box - Put the year of your first ham license

Prize:
Continuing this month we are giving away a set of CD's to one participant according to the following rules:

1. The participant meeting the requirements below and posting the highest score will be the winner of a set of CD's in the following months: July, August, September, October, November, January, February, March, April, and May.
A. Requirements: The participant must be a NAQCC member and can not have won a CD set previously.
B. If the highest scorer does not meet the requirements, then the CD set winner will be the next highest scorer who does meet the requirements.

2. Twice a year - in the December and June sprints, the winner will be a participant drawn at random who meets the requirements in 1A and who makes at least 5 QSO's in the sprint.

3. Club Officers (WY3H (ex-KB3LFC), K3WWP, W2LJ, K5DUZ, KD2MX) are not eligible.

REMEMBER: You HAVE to be a NAQCC member to be eligible to win the CDs; and there's still plenty of time to join before Wednesday night's sprint. To join the NAQCC, please visit:
http://www.arm-tek.net/~yoel//joinup.html

Entry Deadline:
All entries must be RECEIVED before 2400Z on December 18th, 2007. So submit as soon as possible, especially regular mail entries.

NEW! NEW! NEW!
Be sure to use the new NAQCC Sprint Autologger feature! Please visit http://home.alltel.net/johnshan/sprintlog.html after the Sprint to send in your entry!

For further information, please visit:
http://www.arm-tek.net/~yoel//sprint200712.html

Everyone has serial number 2. I have serial number 1 :-)

I really don't understand this fascination with serial number nonsense. I guess it was Elecraft who started it with the K2. Before that, no one put a serial number on kits (except maybe Heathkit).

Steve.

Serial numbers are helpful if you modify or update the equipment.

Elecraft has done extensive mods on their K2 line. I remember buying a used Heathkit DX-60B that had a slight chirp. I call up Heath. They asked me what the serial number was and told me they had modified the B+ filtering and sent me an upgrade kit (I believe it was a resistor and electrolytic capacitor). I still remember them being very helpful after all these years...

2423. History of ATS series

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-11 13:54:18 UTC
From: nn4cw
Topic: 2423 Message: 2423

Ever since reading somewhere that Steve made the first ATS from scavenged parts from a satellite receiver I've always been curious about the history and development of this great little radio. It would be great to hear from Steve about how he came up with the design and a little history behind the development of it. Did he build it from discrete components and then miniaturized with smt components or did it start out with smt components? Did he build the first smd one on a printed circuit board, etc?

Thanks

Gil NN4CW
ATS3 serial numbers 124, 275
ATS2 serial # 102
ATS3A #55 (unbuilt)
ATs3B serial #45 (unbuilt)

I would be interested in a comparison summary of features and/or menu options for each model.

I'll bet someone has one !

Subject: [AT_Sprint] History of ATS series

Ever since reading somewhere that Steve made the first ATS from scavenged parts from a satellite receiver I've always been curious about the history and development of this great little radio. It would be great to hear from Steve about how he came up with the design and a little history behind the development of it. Did he build it from discrete components and then miniaturized with smt components or did it start out with smt components? Did he build the first smd one on a printed circuit board, etc?

Thanks

Gil NN4CW
ATS3 serial numbers 124, 275
ATS2 serial # 102
ATS3A #55 (unbuilt)
ATs3B serial #45 (unbuilt)

2427. Re: [AT_Sprint] History of ATS series

The ATS series started out as a SMT project in an attempt to build a trail friendly rig into an Altoids tin. It was built on two boards which plugged in together, was a dual band 20/40 meter rig with relay switched filters. The PA was a NPN SOT-223 device with a fairly low Ft, so power out wasn't very good, even at 12 volts. Maybe 2 watts on 40 and 1 watt on 20.

Besides the low power output, the most serious problem was mechanical. The two boards were the same size and had common connections along both edges of the boards. Both boards had to be connected together for anything to work, so it was very difficult to trouble shoot if something wasn't working right. Longish jumpers had to be soldered between the boards so they could be placed next to each other, instead of being stacked so it could be worked on.

Dispite this, I put picutres of the rig on my then new web site on qsl.net. It wasn't long before I was getting requests to kit the rig. Since what I had wasn't real practical to kit or build, I went back to work on it.

The breakthrough which made the ATS rigs possible was the invention of the square wave, logic gate driven 2N7000 PA. At last I had a PA which was simple, took up little board space, was effiecent, had consistant power output on different bands, worked at low voltages and used common, inexpensive parts. The second innovation was to use the now familer band filter module boards. I was now able to fit everything on a single board, dispite using mostly 1206 sized passive parts.

As for functions, it only had the basics, because the processor used was an Atmel 90S2313 with only 2K of memory. It had RIT, keyer with one memory, Tune up mode, the push button tuning and frequency annunciation.

Only about 50 of the original ATS rigs were produced.

A year or two later, some new parts became available, or I became aware of them, like the low power AD9834 DDS chip, the TI MPS430 processor and LM4808 low power headphone amplifier. I decided to try these new parts in a new ATS design to see if the current consumption could be significantly reduced. The ATS-1 drew some 50 ma on receive, which was a significant amount of current.

Thus, the ATS-2 was born. With the new parts, receive current dropped to a much more modest 25-26 ma, half of what the ATS-1 took. I also made the board much larger and put it in a plastic box which could also hold AAA batteries. The larger board allowed parts to be spaced farther apart, making it easier to build, adding a few slide switches and little volume control.

With more memory available in the MPS430 processor, DFE mode was added, along with XIT and the calibration modes. 80 meters was also added, making it a 4 band rig, instead of just the three bands the ATS-1 did. (40/30/20)

About 100 of these were produced. I might have did more, but the plastic box which was supplied had the front silk screened. This I did myself, which turned out to be a mistake. Most of them turned out okay, but not great. It was a lot of work. I resolved to go back to the Altoids tin formate. While some liked the larger form factor of the ATS-2, most still wanted the smaller Altoids size rig. Besides, the KX1 came out about then and I wanted to have the smallest, lightest rig there was.

So, back to the Altoids sized rig with the ATS-3, followed by the 3A and finally the 3B, each which had incermental improvments from things learned from the previous design.

Steve:

Nice writeup about the ATS series of rigs. It is obvious that you put lots of thought into the design of these rigs!

I'm the proud owner of one of the original ATS rigs. I guess since it was the first, there's no mention of ATS-1 in the manual which came with it, just ATS. I wasn't aware that there were only 50 or so of them produced. I'm the third owner, the first owner built it, but didn't get around to putting it into an Altoids tin, neither did the second. The second owner found it in a drawer, decided that it was surplus, and sold it to me. He says it is in working condition - all the parts seem intact. I haven't powered it up, so I may be screaming for help if it doesn't seem to work correctly. I have it stashed in a place where it is prominently displayed and will get it into an Altoids tin one of these years! It seems to be a museum piece!

It may have slipped his mind, but Steve did have available a version of firmware for the original ATS that provided Direct Frequency Entry (DFE), since mine has this firmware.

Steve,

Thanks for this nice writeup. Many of us were unaware of the
background behind this amazing series of radios.

I had a hunch that you were influenced by the KX1. I built a KX1
before I knew about your design, and I was pleased with it, until I
built and used your ATS-3A. It's an apples and oranges comparison,
but I think you blew away the competition. The "B" is just a jewel.
I do wonder if you've really saturated your potential market - or if
you care.

In any event, we're all grateful for your work, and for the personal
responses that make being part of this group so much fun.

The 2N7000 final with the square wave drive really is a breakthrough,
compared to the bipolar designs with tuned stages, lots of parts,
etc. Your design's simpler, incredibly efficient, and better.

Thank you!

2432. KD1JV SWR Meter Question: Polarity of LEDs

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-12 13:59:05 UTC
From: kc7fys
Topic: 2432 Message: 2432

My question is about the rectangular LEDs in the Altoids-friendly SWR meter Steve designed, anybody who built this, could you tell me if flat side of the circles on the PCB indicates the LONG or SHORT lead of the LEDs? Or is this not critical?
Thanks,
Jonathan

And if that doesn't work, try reversing the direction. Seems to me I recall, at least with a batch from Steve's original kits, that there was a silk-screening error that had them backwards.

Thanks Mike and others.
I got it. I had to remove all the LEDs. Gave my wife a chance to get into ham radio with the solder sucker. She's a good sport.
Thanks. Like all Steve's kits--I hate to put this in an Altoids tin! It's too nice.

It nice to know the history, but my bigger concern is with the FUTURE of the radio. I use this radio while backpacking, and while there are substitutes for it as a trail friendly radio, there is arguably (?) no GOOD substitute for it. I don't know of any rig that has the same size/weight/features mix, or even comes close to it.

If the ATS ceases to be an available kit soon (as seems likely), those of us who put it in our backpacks will certainly want to make sure that one is available to us many years down the road. That's mostly why I decided to also build the 3B even though I am quite happy with the 3A. Hopefully, someone will decide to kit the rig on an ongoing basis once Steve moves on from it.

And since it's the Holiday Season: I wish for the perfect companion to the ATS--an auto tuner in an Altoids tin, with a tuning range that is at least equal to the Elecraft T1. On the trail, THAT would be a truly awesome set-up! Now, I don't know if it's possible, but if anyone could do it .

An autotuner. YIKES! That would be awesome but
me thinks it might be hard to fit the toroids
in an Altoids tin.

Each iteration of the rig had improvements over
the one before it. Several of Steve's earlier
designs are available, (Not ATS) elsewhere.

If the 3B is as far as the design can go, I suspect
he might allow someone to carry it on if he is not
interested in the future.
If one misses out on an offering, it's ashame but they
just have to be patient for the next project.

It's interesting about cases--because after assembling the T1, I have the same complaints about the case as others have had. Nothing about it says, "Hey, I put that together myself," like the ATS3. On the other hand so many have also said that such a premium piece of equipment as the Bee shouldn't find itself in a lowly breath mint can. Perhaps that's the irony--it's the Maxwell Smart Shoephone of the QRP world. There's something about the subtle beauty of the Altoids tin.

I'm ok with the T1 case, and the thing works great. It's just that it is far larger than the ATS, which just seems wrong. A companion tuner to the ATS that has the functionality of the T1 (or maybe fewer bells and whistles) but has a similar size and weight as the ATS would be very nice. I currently use the Altoids tuner with the jumpers that Steve designed. It works well enough, but the jumpers are somewhat tedious. Later interations of that tuner with toggle switches make the package significantly larger. But, as noted here, an auto tuner in an Altoids might not be feasible.

Would folks pay the price of a K-1 for an ATS rig? It seems that the K-1 is the nearest competition to the ATS, but it costs considerably more, especially if you want all its features and band modules.?

Maybe Steve is doing us a favor by making the kits very near his cost, since there's nothing on the market with anything near the features at anything near the price. I haven't priced the components on a one up basis, but his price seems very reasonable.

The Altoids tin as a case may appear to some to be less than optimum appearance wise but if so it may just be that you're not trying hard enough. 9>) Have a look at some of these.

http://steampunkworkshop.com/altoid-etch.shtml.

They are not perfect but they sure are interesting and different. You're only limited by your imagination.

Another formative fact about the ATS series is Mr. Weber's rather rich and varied hiking experience, and his considerable volume of hiking tips given on his online journal <http://www.trailjournals.com/entry.cfm?trailname=5660>. Lightweight mobility is an absolute necessity for hikers covering hundreds of miles. Those who have been here with the ATS for years know this--but it's an obvious fact not often mentioned. I have been scanning through the trail journal myself, and it's reaffirming to me that good hams have a full life off-the-air!
It's a good read, and puts the ATS3B in better context.

Topic: 2423 Message: 2443

Not sure if anyone has used one of these but this is what I am going to use for my ATS when I get around to building it. I have already gotten the enclosure and it is TOP NOTCH. AA-1 means alternative to Altoids Tin if someone wants something that is a bit more of a real enclosure. I am not knocking the Altoids method , I just wanted something a bit more sturdy and befitting of the price and performance of this rig. Now all I have to do is find someone to build it for me ;-)

>Altoids Tin if someone wants something that is a bit more of a real

The AA1 is a nice box, but it is less than ideal for a ATS rig, primarly due to its somewhat thick walls.

Since the rig was designed to go into an Altoids tin, it really is the ideal enclosuer for it. With a little work, it can be made to look quite nice and seems to be much of the fun, seeing what some of you have done.

>and whistles) but has a similar size and weight as the ATS would be

The major obstical to a really small auto tuner is the relays. Until
someone makes really tiny latching relays, it just won't fit. TO-5 sized
ones would be great. They do make TO-5 sized relays, but not latching ones
and they are very expensive (like 20 bucks a pop!)

Maybe from an aesthetic standpoint but methinks if I'm taking this thing out in the woods, tossing it around in a pack and generally beating the hell out of it I want something that's tough and repels water.

<http://pelican.com/cases_detail.php?Case=1010>

Altoids tins are novel and OK for "indoor" use, but out in the field I'd want something a lot more robust. If you're clever you could probably fit all the band modules, some ear buds and some micro paddles in the above mentioned case, making it one-box fits-all solution.

I'll post some photos of my ATS-3A in the AA-1 enclosure when I get a chance.

As Steve noted, the walls are a bit thick so the downside is that the jacks on the circuit board don't protrude all of the way through the side of the enclosure as they would with an Altoids tin so I had to make the holes a much bigger diameter than I would have liked to accomodate the jacks for power/phones and paddle. Still it works ok and with the pivoting top (bottom in this application) it makes band changes a snap.

Kristinn,

Just monitor this group and Steve usually posts
in advance when he will accept orders. Will also post
estimates in advance as to how long it will be before
he is going to do a run. He doesn't like prepayment
as it is a chore to keep track of who's paid what.
Plus, I think he wasn't big on "waiting" lists
either. He already said he'll be making this little
radio for some time to come so be patient.

2454. Trouble with new ATS-3a

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-13 22:23:18 UTC
From: lownslow1601
Topic: 2454 Message: 2454

When I received my ATS-3B kit, I realized it was time I sucked it up and assembled my ATS-3a kit! I built it with a soldering iron, rather than using the Cash Olsen technique. Assembly went well and when I plugged in the 40m filter board, the receiver worked and the transmitter put out about 2.5 to 3 watts with the power supply set at 9v DC. The only anomaly I noticed was that the output would occasionally drop to about 1.5 to 2 watts and then go back up to near 3 watts. I poked around, but couldn't determine the reason for this phenomenon.

When I had the 20m filter board completed, I plugged it in to make the adjustments and discovered that the transmitter was no longer putting out any power. The side tone was present and other functions seemed to be working. Then I noticed that the receiver had also stopped working. The radio would still recognize different filter boards, though, so I thought the uP was working OK. I referred to the chart of voltages, provided in the manual, and checked IC voltages pin for pin. I found a few discrepancies with no filter board plugged in and a supply voltage of 9.0v DC.

U6: pin 3 was 3.50v, rather than 0v, and pin 17 was 3.50v, rather than 0v.
U7: pin 20 was 0.49v, rather than 0.75v.

There were no voltages on Q6, 7, and 8.

As I was taking the voltage readings, I accidentally bumped the dash side of my paddle and the side tone came on and didn't stop. I found that if I hit the dot paddle, the side tone stopped. This observation alarmed me, because I thought that things were continuing to fail in the radio.

I looked the radio over carefully. There are no burned or broken components that I can see. Since one commonality between the receiver and the transmitter is the output filter, I looked that over and it looks OK.

Suggestions? Thanks and 72/73, Dave K1YHR.

have any of you come up with a solution for keeping the rig generally water resistant? Whether in an Altoids tin or something else, my concern is moisture/dust getting into the holes for the buttons. I'm sure some sort of 'boot' that fits over the buttons and seals to the container would work. Where to start looking for something like this?

The jacks present another issue but I imagine using small o-rings that press between the container and the jack on the inside of the chassis.

By the way, last night I had time to make my first ATS-3B QSO, with a station up in White Salmon, WA on 80m, about 535 miles as the aether flies. I hadn't even adjusted my SWR (which must have been around 2:1 into the Butternut HF6V) nor had I peaked the power output of the band filter module. My output was 3watts to the antenna. He gave me a 599 "pounding in here" report along with clean keying and signal characteristics. Not long after that I had a station just over the hill in Berkeley call me. What a blast!

My ATS-3B sits in a 'prototype Altoids tin. I had stripped all the paint from it. The holes, based on the manual template, were off some. But I just wanted something to put it in until I have time to get a perfectly-drilled container going. And as I said, I'm hoping to keep it mostly water resistant, since taking it to the beach (along with our water-loving dog) means seawater and sand. :)

I'm so happy I put this rig together. Possibly the most fun I've had in ham radio in ages.

I've ordered the rail-to-rail op amp to build a computer interface. Anyone else have any caveats on this? How did you mount it (in the ATS case or outside?)?

I have my ATS-3B installed in a AA-1 enclosure and find it to be very rugged. I was concerned that a Altoids tin wouldn't hold up to my brand of punishment. I also conformal coated my board using HumiSeal. It sprays on, but be sure to mask off anything you don't want coated
(switches, ground pads, trimmer caps, connectors, etc.). I wouldn't submerge it, but it gives me piece of mind if the radio is n my bag when it starts raining.

Some how the rig got into Tune mode, likely because the menu and then the split button got bumped while handling the board.

Intermitents like you discribe are usually caused by a missing solder connection. There is enough friction contact to make it work intially, then after a little handling, it goes open. Look at the DDS chip and associtated parts, including the clock oscillator.

I put my ATS-3A in the AA-1 enclosure. The thicker walls of the hogged-out box did require a little more work than the Altoids box, but the end result is a very sturdy little radio.

To be able to get the connector end of the board close enough to the box wall so that the plugs would all seat properly, I had to resort to my Dremel tool with a small grinding wheel on it. Check out the pictures listed in the Photo file under the heading "N6GA's scope fotos".

I don't have the B model so I can't speculate on what issues might arise using this enclosure with it.

Personally I don't worry about it, but then I don't go to the beach or have a wet dog :-) On the trail, the rig is deep inside my pack and I make darn sure nothing inside my pack gets wet.

How about simply using a quart sized zip lock storage bag for those occasions when you might want to protect it from the elements? The bag can be mostly sealed, just needing a small opening to let the cables out of the side.

You can keep incidental grim out of the switch holes and possibly the jack holes by placing some thin felt over the switches. Wal-Mart sells some suitable matterial in the crafts department. For the switches, I just cut a small slit into the felt and push the switch post threw the slot.

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-15 06:21:45 UTC
From: Tim Keene
Topic: 2461 Message: 2461

I have a question for Steve. Why is the max voltage input into the QSBA 15V? Is it because it will make the QSBA put out more than 12v to the ATS-x or is it to keep the regulators cooler? The reason I ask is because I put my ATS-3 and QSBA into one small box (one of those tin xmas boxes from Big Lots for less than $2 bucks), and I was planning on putting 12, 2700mahr "AA" batteries under the cover to make a completely self contained rig in one box. When the batteries are working at the nominal voltage of 1.2v each it is only 14.4v. But when they are freshly charged they are actually at about 1.4v each which would be 16.8V. From what I read it seems the LM-317 and 7805 can take that voltage no problem but I would like to make sure. I would like to find out what you and everyone else on the site think.

There is a cap across the DC in which is only rated for 16 volts, but 16.8
should not be a problem. I'd put a heat sink on the '317 too.

2463. Deaf AT-Sprint- Any Suggestions?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-16 03:50:53 UTC
From: kg0ew
Topic: 2463 Message: 2463

My little ATS-3A has been ambling to life for some time now. first had a bad U1 that needed replacment. Now its on the air, but with far less receive sensitivity than I expected.
I've completed the 40m and 30m band boards, both work, and Tx output is over 5w with 12V (measured with a LP-100 wattmeter). That would lead me to believe the band board is working well, except...
When I connect the antenna in directly to pin 1 of the band board, the receiver is much hotter (noisier too, but I can hear a lot of week signals I can't hear going through the filter).
I spent a lot of time tweaking CT2 and CT3, so I don't think it is as simple as peaking these two caps.
So... any ideas on what could be causing so my loss in receive, but not on transmit?
Thanks for any and all suggestions!

Tim,

If you really want 12V from your QBSA, it's easy. I posted a Word document in the FILES section here a long time ago about that. You'll need about 15V input to keep the regulator from dropping out of regulation with 12V out.

Have you thought about running the ATS rig off 8 or 9 cells, direct, without going through the adjustable regulator in the QBSA? The QBSA by itself will run fine from the lower voltage. This would raise the overall efficiency of the unit, and the weight would be reduced.

I think the only thing you would lose is the ability to reduce the voltage to the rig, to reduce the output. With a switch you could run in either mode - direct, or through the QBSA's regulator.

Don't run the ATS on 12 cells direct. That's too high.

I can't see adding 3 or 4 extra cells so you can waste 3V or more in the protection diode and the LM317T; but if you don't plan to carry it out on the trail, it really doesn't matter how you do it.

Thanks for the additional info and I forgot there was a mod for the QBSA to make it go up to 12V. I'll take a look at it but probably will not do it....but who knows?? I have pretty much already done and/or considered all the possible combos for powering my ATS-3 before getting the QBSA. Now I'm just trying a few more since I now have both units installed in the same little box. Before getting the QBSA I pretty much always used my Planters cashew can (nothing but the best hi hi) which has 6 Hawker Cyclon 2.5AH batteries which are 2v each. When fully charged they generally stay up between 12.3 and 12.6 volts. It's alittle higher than Steve recommends but I have had no problems with it. Of course I always tune my antenna first with my MFJ analyzer so It never sees a high SWR. I still have the power connector on the ATS to plug in directly so I still have lots of options. Since I don't do any real trail hiking anymore, weight is not really a factor for me. I occasionally go out on day/picnic trips to where ever and throw up a long wire. Most of my QRP work is here at home anyway. It's a great change of pace and challenge from the 100w or more rigs.

From: Tim Keene
Topic: 2467 Message: 2467

One more bit of info. I never have tweeked my coils to get full output pwr so the most my rig puts out on any of the bands is about 4w or less so the finals probably run cooler on the higher voltage.
Tim

>less receive sensitivity than I expected.

There are two possabilities. One, the link and secondary turns on LF3 are reversed. This is a common problem. This is likely the problem if CT3 does not produce a peak in the tuning.

Second, there could be a problem with the QSK switches, likely a bad connection or damage to one of the 2N7002 fets when soldering. If you jumper pins 1 and 2 of the filter board socket, then put the antenna to pin 5 and receive sensitivity is still bad, then look at the connections to C47 and Q2.

New guy question: So far in my short ham career I have built 3 kits - an OHR QRP wattmeter, a T-1 tuner (Elecraft), and the ATS-3B. All use different connectors. It seems to me that for QRP/portable ops it would make sense to standardize on one type to keep things simple. Do you folks use various types or do you try to stick with one kind? If just one, which and why?

Thanks es 72,

Hi,

What do you mean? The connectors for the jacks and
such are pretty much the same on the little QRP kits.
The BNC connector for the antenna goes without saying
as it it small.

Carey,
Other than durability and stiffness, was anything gained electronically with the use of thicker magnet wire on most of the toroids in the filter board?

BTW, I followed your suggestion of the two flow stage of constructing the main board. After pasting the passive components on the higher parts count side, I could see potential problems for me disturbing pasted resistors and caps while placing some of the IC's in the tight spots, especially after several cups of QRO coffee. It worked like a charm.

I should have been more specific - I'm referring to the connections
from the radio to the antenna, including whatever is in between, like
a
tuner or wattmeter. The ATS uses an RCA connector. My wattmeter
uses
SO-239's. The T-1 tuner uses BNC.

Bear in mind I'm new at this. I have looked through a few books and
can't seem to find a guide as to whether the different types fit
different applications. It makes sense to me that the ATS uses an
RCA
connector because if the wire connected to it were inadvertantly
yanked, it would just come loose rather than ripping the jack out of
the Altoids tin. On the other hand, a BNC would be less likely to
come
loose by itself since it locks. Or...am I overthinking this and
should
just use whatever I have in my junk box?

Tnx.

Tim

Tim,

I have lots of portable QRP rigs and I've standardized on BNC connectors. They're small, qualified for RF and easy to insert and remove. They also come in crimp as well as screw on models and are made for al popular coax sizes - RG-174, RG-58, RG-59, RG-6, etc.

RCA connectors vary in quality and are not meant for multiple insertions and removals (the shield body may become intemittent as it spreads).

If you're concerned about yanking it loose, just insert the BNC without turning the bayonet lock.

73,

Mike N2MS

If I have a choice, (I'm retrofitting or assembling) I use SMA.
Otherwise BNC. You're right, if you don't settle on something
you're going to always have mismatched innies and outies, and
it's a real PITA to always need adapter cables or connectors.

Seems everyone has different needs and uses. Personally I prefer the RCAs for my trail gear as BNCs and SO239s just add unnecessary weight! But at home I use all three. So I keep adapters of all kinds around. Several folks have used BNCs instead of the RCA jack shipped with the kit ...Install your own flavor of connector?

Gil,

Glad to hear you got through the assembly!

I used mostly #26 wire for the many toroids for which #30 was supplied with the "B" kit. I did this for five reasons:

1) I like winding, stripping, and soldering #26 better.
2) The modules are vulnerable in the field, and #26 is more durable to accidental abuse.
3) Steve supplied #26 with the "A" kit for the same toroids.
4) #26 stays put better when you spread or tighten the turns.
5) The Q is higher with larger wire. Even on my Heath QM-1 I can see an improvement with #26 compared to #30, but it's not a big deal. I don't know if there's a significant effect on efficiency or power output. I was somewhat primed about this because I think I can feel a slight rise in temperature for some of the toroids on the higher frequency modules of my "A" kit, and they're done with #26. #30 won't be better.

I posted a detailed document describing my modifications to the modules here in the "FILES" section. All of you who're seeing low power on 40M should at least look at it. I think my notes will apply to either #26 or #30 wire - the spread of the turns can take care of the small differences in tuning.

The rig will deliver great performance on every band if you give those modules some TLC.

--- In AT_Sprint@yahoogroups.com, "Tim" <bipetype@...> wrote:

Tim,

I'll second most of what's already been said here about the RF connectors. I think Steve made a good choice with the RCA, because he wanted a trail radio with minimum weight. If you use BNC, the male BNC that connects to the radio adds significant weight; together a male and female BNC weigh more than 1 ounce. The RCA's are a small fraction of that. The torque required to mate the BNC's is excessive for the tin box. RCA plugs can be adjusted so you have the mating force you want.

Consider getting the optional BNC female jacks (OP-SB2) for your OHR WM-2. UHF connectors are too big for that meter. Most of us have accepted that UHF connectors (SO-239, PL-259) are mediocre at best. They're always a hassle.

Type N, BNC, SMA, and many other RF connectors all offer advantages and disadvantages. SMB would be a great QRP-portable connector, because it's tiny, and you just snap it on. Of course they cost more...

This link will give you something to think about. There are so many kinds of coaxial connectors that most of us can't keep track of them any more:

http://www.amphenolrf.com/products.asp?N=0&sid=4765BC007A52E17F&

Over time your collection of treasured coaxial adapters will grow. Almost any combination of sexes and connectors you can imagine is available these days.

2487. Wider passband for 3B?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-18 15:22:34 UTC
From: mpupeza
Topic: 2487 Message: 2487

Is there an easy way to widen the audio passband for easier
listening
- temporarily?
My crystals must have been a good batch,because my audio passband is
200Hz at 6 dB and 400Hz at 20 dB. I'm finding it kind of tinny, or
almost ringing and hard listening while scanning.
Can I put a jumper, or small switch with some component, accessible
from the band filter side, to make the audio wider?
Then, when needed, just pull a jumper, or a miniswitch to make it
normal again!
But, WOW, what a hot receiver! ANYTHING that I can hear with my IC-
703 is good in the ATS-3B.

2490. Wire size?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-18 20:25:18 UTC
From: Tiana
Topic: 2490 Message: 2490

Looking over resent messages about changing the wire size from 30 to 26 on some toroids I wonder if can use a different wire size in a current project I messed up. I bought a 40 m tunner upper kit from Norcal. Since I'm very new to kit making I wanted to have some experience with smt soldering before I built my ATS 3B. And I wante to be able to tune without having to use the rig. I soldered in one of the toriods in the kit wrong and when I desoldered I broke the wire. I'm pretty sure the wire is size 28 because I compared it with the 30 and 26 wire I have. I've ordered #28 wire but I haven't gotten it yet. Could I rewind the toroid with 30 or 26 wire? Or should I wait until the #28 wire arrives?

Thanks,

Tiana KE5ODX

I'll do you 2 better. I'd trade my original ATS (no suffix) for the
built 3B. :) :)

Tiana,

For that kit you may be OK to substitute #30 instead of #28 wire. If it's one of the toroids with the primary and secondary, T1 or T2, going to smaller wire should work OK. I'm not sure whether #26 would fit, however. I have this kit also.

If the toroid in question is L1, better stick with the original wire, since that one is a specific inductance for a tuned filter, unless you have some way to measure it.

You could try it and later correct it with #28, as long as you use no glue.

Should make virtually no difference, as long as you can fit the turns on
the core! Try 26 first!

Guys;
I haven't had any real responses from the group yet!
I've tried shorting X4 and X3 and bypassing them with a 680 pF cap, but neither of those helped. Just put humps in the passband. Maybe a resistor from C4 to C8? Or a cap?
I've posted a spectogram picture of my bandwidth in the Files section, so you can see how narrow this guy is! Great for crowded conditions, but hard to listen to for me! I'll try a few more things, but any help would be appreciated.
Thanks.

You could try bypassing all 4 IF crystals ala the ATS3
BUT since the current design is setup to match the
input/output impedances for the IF filter, you likely
will get strange results.

Mike,

I found that the audio sounds better if you run into higher impedance phones, or a resistive pad, rather than the low-Z phones. The lower the load impedance on the audio stage, the sharper it gets.

I did some tests to prove this. The resonant frequency also shifts up a bit as the load Z goes down. It's no big deal.

2498. Building my 2nd B

Yahoo group: AT_Sprint (2002 — 2008)

From: w1mt
Topic: 2498 Message: 2498

Here is a little story of building my second B. I again used the hot air method and it is the only way to go as far as I am concerned. Highly recommended. I did the most populated side of the board first this time and it went well. Had a few solder bridges that I took care of real quick with braid.

Powered up and found that some of the leds on the display did not light up. Hmmmmm. Power seemed adequate so check the mpu port pins and sure enough a couple of the legs of the mpu were up off the board. Note to self make sure that the legs are parallel in the same plane next time -- perhaps this was a results of opening the packages too fast. Reflowed the mpu with the embossing gun and got those pins all down and looking nice. Repower and now all I hear is a steady whoosh but no sidetone or led display. Hmmmmm. Reinspect the mpu to make sure that each pin is down. Check looks good. Start checking voltages on the led port pins. All looks good. Ok, now start at pin 1 of the MPU and check each pin. Wow, one of the crystal ports is at ground. Not good. Inspection of the crystal reveals that I left the leads too short and the case was shorting to the hole ring around one for of the holes. Try to raise the crystal a little and it works. Led lights and sidetone rings, very nice. Put the wire holddown back on and power up and just a steady whoosh. Darn, pushed the crystal case back onto the ring again shorting one side of the crystal again. Worked on it some more trying to get some more separation between the case and the hole ring but worked it too much and broke the lead at the crystal. Thanks to Steve I got a replacement and put it in tonight and it works FB again. Thanks again Steve!

Moral of the story: Leave those crystal leads a little long so the case doesn't short one of the leads. :)

Have a very Merry Christmas.

Junpering out crystals in the filter does little but make the opposite sideband rejection less. Reducing the value of the caps to ground between the crystals would be the best bet. The one in series with the RFC to the 1st mixer is series resonante at 5 MHz, so if you change that cap, the RFC value should be changed also to keep it series resonate at the IF frequency.

Also, changing the cap values will shift the center frequency of the filter, so it will have to be recalibrated to put the IF frequency in the ideal spot.

4.915 MHz filters are inherently fairly narrow and the cyrstals are matched to +/- 10 Hz or better.

The audio filter by its self isn't too narrow, its primary job is to eliminate hiss and lows.

Steve,

Thanks for this insight. I think the crystal filter is just perfect for what we use the rig for. Everyone has some personal preference, but I think it's nice.

The audio passband sharpens when a low-Z load, like 8 ohms, is connected to the headphone amp. Some small headphones are this low with both elements connected in parallel.

The resonant frequency of the audio peak also shifts up about 50 or 60 hz, just enough to notice, as the audio load is varied down from 100 ohms to 30 ohms or lower. The audio load can be a pure resistor, and the effect is the same as with phones. I measured it with an audio generator and an AC voltmeter; that eliminates crystal filter effects.

It's not clear to me why this happens. Most people who measure the rig with Spectrogram use a high-Z load, so they miss the effect.

I decided to like it rather than fight it. The additional audio selectivity is OK for weak signals, and when the signals are strong, my inline volume control raises the audio load to about 100 ohms, so the peaking is reduced.

I'm curious whether you see this peaking and shift if you measure your rig's audio passband with a really low Z audio load. Both my ATS-3A and ATS-3B have the same effect.

This just isn't a big deal - it's just a little thing some of us have wondered about. Maybe someone will tell us about some higher-Z headphones that work better than what we use.

I did learn that the headphone elements should not be put in series to create a higher-Z combination - they will be out of phase unless you rewire the headset. Out of phase audio sounds odd, more spread out, than in phase, which is more centered. Wiring some phones for series, in phase operation is a possibility to try some time.

The QBSA eliminates the effect, as you would expect, because it's a high-Z audio load!

The led display is fine to use the hot air on. I have
done two that way with no problem.

All thru hole parts are done the old fashioned way
with iron and solder.

--- In AT_Sprint@yahoogroups.com, Steven Weber <kd1jv@...> wrote:

Steve,

I measured the audio passband of my ATS-3B. Audio was injected through a 100 uf cap at TP2. The level was set to produce a maximum level of about .08V RMS at the headphone jack output. I believe this level is below the AGC threshold. The frequency was varied, and the output was measured across the audio passband from 200 to 1600 Hz. Data were taken for three load conditions at the output: Hi-Z, 51 ohms, and 10 ohms.

The injection level was chosen to create an output reading corresponding to 0 db on the HP400D meter at the audio bandpass peak. All readings were taken in db relative to that level. The db readings were plotted on a graph.

My ATS-3B has 560 pf NPO caps added to C20 and C21. These lower the peak frequency of the audio passband slightly. This is the only mod to the audio chain.

With a Hi-Z load my peak frequency is about 590 Hz, the 3 db bandwidth is about 130 Hz, the 10 db bandwidth is about 375 Hz, and the Q is about 4.5.

With a 10 ohm load my audio peak is at about 640 Hz, the 3 db bandwidth is about 107 Hz, the 10 db bandwidth is about 330 Hz, and the Q is about 6.

The results for the 51 ohm load are in between these two sets - I never plotted them.

So the audio peak shifts up in frequency when Lo-Z phones are used, it sharpens somewhat, but it's no big deal. Just an interesting effect some of us can hear. I have a hunch that L6 may play a part in this effect.

Others may want to try increasing C20 and C21 to lower the center audio frequency. Some operators prefer a lower tone. I did this so I'd be closer to 600 Hz. With no added caps I was close to 700 Hz when using low-Z phones, and that's near the side of the IF passband. I sure like the sound I ended up with. Perhaps the tolerances for C20 and C21 allow some variation.

2506. Filter Module Storage Breakthrough

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-20 20:50:58 UTC
From: radio_kx0r
Topic: 2506 Message: 2506

All,

Everyone with an ATS rig has found ways to store and carry the filter modules. Some ways are better than others.

Recently I ordered some tin boxes from Specialty Bottle Supply.

http://www.specialtybottle.com/index.asp

K6JF brought this supplier to our attention. They are easy to deal with, do small orders, take PayPal, etc.

They sell a THN4 box similar to the Altoids tin for $0.64 each. When I ordered some of these for future projects, I ordered some smaller THN2 boxes as well.

The THN2 is a rectangular tin 2.5" by 2". The bottom and top are convex, and it has a hinged lid with a snap catch like the Altoids box. These also cost $0.64 each in small quantity.

Today I discovered that four ATS-3B filter modules will fit inside one of these tins. The lid snaps perfectly, and the fit is so good that there's almost no rattle.

It's a nice puzzle to figure out how to fit them in. The key is that the boards lie back-to-back, so any rubbing happens on the soldered side. The header pins point into the bottom and top of the tin, so they won't damage other modules. I don't think there's much room for padding, but it might be possible to add a little thin felt or foam to reduce rattling. The fit is so perfect it's like the tin was made for our modules. The THN2 tin with four modules weighs about 1-1/2 ounces.

If you carry less than four modules in the tin you'll definitely need some padding.

For my ATS-3A I went to some trouble to mount three filter modules in the lid of the rig's Altoids box. The fit's nice, but changing filters takes longer than I like. The THN2 is a MUCH better solution. It's made for the job.

I also ordered a larger tin called THN8. These have a clear window, measure 5.25" X 3.38" X about .8". One of these would hold an ATS rig, a tuner, filter modules, or maybe batteries, etc. They look nice and only cost $.80 each. These should interest people who want more stuff in one box.

Steve, maybe you could put that SSB rig in one of these!

2507. Pin-out of U5

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-20 23:01:22 UTC
From: nn4cw
Topic: 2507 Message: 2507

In measuring voltages on U5, I used what I thought was convention and counted CCW from the corner of the IC in the lower left hand corner with the writing on the IC properly oriented for reading. This I thought was pin 1. Most of readings were off what was specified in the manual for the first run. However, the readings were close to the specs, but not in corresponding order. I checked the readings on one of my ATS3's U5 (or equivalent) and they approximately corresponded with the readings on the Bee's U5. I searched in the archives and found a reference that the order of pins differed in this IC from conventional, but I didn't see the proper order. Could someone please give me a heads-up on the correct order for future reference? Tnx.
73, Gil

2509. RE: [AT_Sprint] Pin-out of U5

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-20 23:26:45 UTC
From: Rob May
Topic: 2507 Message: 2509

Gil,
It's number conventionally. Here's a link to the datasheet:
http://focus.ti.com/lit/ds/symlink/sn74lvc1g3157.pdf

On the ATS-3 board it looks like this (with power, phone and key jacks to the left):

_
1| |6
2| |5
3|_|4

Subject: [AT_Sprint] Pin-out of U5

In measuring voltages on U5, I used what I thought was convention and

counted CCW from the corner of the IC in the lower left hand corner

with the writing on the IC properly oriented for reading. This I

thought was pin 1. Most of readings were off what was specified in the

manual for the first run. However, the readings were close to the

specs, but not in corresponding order. I checked the readings on one

of my ATS3's U5 (or equivalent) and they approximately corresponded

with the readings on the Bee's U5. I searched in the archives and

found a reference that the order of pins differed in this IC from

conventional, but I didn't see the proper order. Could someone please

give me a heads-up on the correct order for future reference? Tnx.

73, Gil

--- In AT_Sprint@yahoogroups.com, AT_Sprint@yahoogroups.com wrote:

For those of you who're interested, I just uploaded a graph of the audio response of my ATS-3B into the FILES section of this site. One file is the whole graph, with curves for a high-Z audio load and also for a 10-ohm audio load.

The "Detail" file is a zoom-in of the interesting part of the graph.

My ATS-3B has 560 pf of additional capacitance across audio filter caps C20 and C21 (both nominal .01 uf), which lowers the audio bandpass center frequency a little bit. The effects shown in the graph occur with or without the additional capacitance.

Steve may never see these because the files are large - sorry Steve. The summary in my previous message today applies to these curves.

Oops, my bad Gil. From the original post, I thought he was talking about u5 on the ATS-3.
Ok, here's what the datasheet says, but it doesn't agree with what's in the 'B manual troubleshooting section.
http://www.ortodoxism.ro/datasheets/panasonic/SDE00002CEB.pdf

3 4 5

____
|___|
2 1

Pin
1 Vcc
2 Det
3 Input
4 Gnd
5 Output

My 'B (with no antenna connected):
1 4.97
2 0
3 2.46
4 0
5 1.28
Seems to agree with datasheet

Manual says:
1 Audio in 1.3
2 Gnd 0
3 Audio out .96
4 Vagc (Det) .34
5 Vcc 5.0

I hope this is more helpful than confusing.

2518. Wanted: recipe for German Stoolun

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-21 01:05:30 UTC
From: Steven Weber
Topic: 2487 Message: 2518

One of my fondest childhood memories of Christmas is that of eating the freash baked German Stoolun (I'm sure I'm not spelling that right, but thats how is sounds!) that my mother used to make. I used to love that bread, almost as much as the Snickerdoole cookies.

I was wondering if one of our German friends here could post the recipe? I'd like to try and make one :-) For those who wonder what this is, its a bread with friuts and nuts baked into it and topped with powdered suger. Sort of like a friut cake, but much better.

Hi,

The name is Stollen for the German Christmas cake.
I have no recipe but you might be able to find it
in a store.
One of my co-workers mother makes a mean German
fruit cake that is nothing like the garbage fruit
cakes
comedians joke about. Her grandmother brought the
secret recipe over from Germany. I was surprised when
I heard she made fruit cakes instead of Stollen.

2520. German Stollen

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-21 01:24:56 UTC
From: W4WLC
Topic: 2520 Message: 2520

I am not German but I found the recipe.
☐
Merry Christmas,
73,

W4WLC
Dave

1 1/2 cups raisins
1 cup golden raisins
1 cup candied fruit
1 cup chopped blanched almonds
1/2 cup dark rum
2 envelopes dried powdered yeast
1/2 cup lukewarm water
2 cups milk
1 teaspoon salt
1 tablespoon butter
Grated rind of 1 orange
6 - 7 cups flour
1/2 teaspoon nutmeg
1 teaspoon cardamom
4 eggs, lightly beaten
1 cup sugar
1/2 cup melted butter to brush over dough
Confectioner's sugar to dust top of dough

METHOD
Night before: Soak raisins, candied fruit and almonds in rum. Keep at room temperature. In the morning, drain and set aside, reserving rum.
Dissolve yeast in warm water.
Scald milk with 1 tablespoon sugar, salt, butter and orange zest. Stir in rum. Cool to lukewarm.
Sift together flour, nutmeg and cardamom.
When milk has cooled, stir in yeast and 2 cups of flour. Mix well and set in warm draft-free place for 15 - 30 minutes.
Stir in lightly beaten eggs and sugar. Gradually mix in remaining 4 to 5 cups flour. Dough should be soft, but not sticky, just dry enough to be handled. Knead dough on a floured work surface for 5 minutes.
Place dough in lightly greased bowl, cover and put in draft-free spot until doubled in bulk, about 2 hours.
Punch dough down, return to floured work surface and add dried fruit and nuts, and work into dough while kneading. Fruits and nuts should be evenly worked into dough. Knead until dough is smooth and elastic.
Cut into three equal pieces. Roll or flatten each piece into an oval 3/4 inch thick, pinching the ends to close.

Brush top of each with melted butter and sprinkle with a little sugar. Place loaves on buttered baking sheet or jelly-roll pan. Covered loosely, and leave in warm place for about 30 minutes to 1 hour or until risen about 2/3 larger.
Preheat oven to 350°F.
Bake loaves for 35 - 45 minutes, or until loaves turn golden brown.
Brush with butter and dust with confectioner's sugar. Let cool on wire racks

Wrap tightly in foil and keep in a cool place for 2 to 3 weeks to ripen.
When ready to serve, dust with another sprinkling of confectioner's sugar.

From: ak3f
Topic: 2531 Message: 2531

i am building my 3B and have a question about L4 on the front side of the board.

it is supposed to have a yellow sticker and should be 0.15 uH. but the only part i have left that appears to be an inductor is a same size part with a green cellophane carrier cover, and it seems to measure about 0.23 uH.

the only other inductors had orange and pink tabs. i don't think i confused them. the orange and pink quantities matched, too.

is this different L4 a problem?

thanks for the help,
mike ak3f

Klaus,

I couldn't find a recipe on the above site, but they would have been happy to sell me one already baked. I did the google search and printed out the top three recipes, bought what they called for and went to visit my friend Vivian up at the lodge where I help out in the summer. She looked over the three recipes and picked the one that looked the easiest to make with what we had.

We mixed up the ingredents yesterday afternoon and since it had to sit overnight to rise, she baked it this morning. By the time I got back up the hill to the lodge, it was cool enough to sample and it tasted pretty good. She actually baked it as two loafs, so I'll have one to take to Christmas dinner with some friends.

Next year we'll plan ahead better and make some with enough time to let them sit and "rippen" for a couple of weeks.

Process of elimination, yes that is the .15 uhy part. I changed the color on the layout diagram for better contrast, but forgot to change it in all the other places it was referenced. The mistake was eventually corrected.

Thanks for the suggestions, Steve. Indeed, the radio was in the tune mode. I carefully looked, with magnification, in the areas that you suggested and I did not see anything suspicious. So, I reheated many solder joints and the receiver is now functioning, except that it is very insensitive. I tried retuning the 40 and 20m filter boards. There was some improvement. When I turn the trimmer caps, I can hear the signal rise and fall, yet as I continue to turn, the peaks do not seem to rise any further. Does the capacitance of these trimmers continue to rise or fall as you turn in one direction or does it run through the entire range of values and keep repeating? I tried to measure the capacitance in circuit without success.

I checked the number of turns on each of the toroids on the filter boards and they are correct (I scanned them on my flatbed scanner and counted the turns on a cropped print of the scan file. What a great idea!). The keyer, side tone, etc. seem to be fine. The transmitter still puts out no detectable RF signal.

I hope you have a great holiday and a happy, successful 2008. 72/73, Dave K1YHR.

Topic: 2454 Message: 2536

Dave K1YHR
The trimmer capacitors go from minimum to maximum capacitance in 180 degrees, then back to minimum in the other 180 degrees.
That means that there 'should' be 2 peaks every 360 degrees, or 1 complete turn of the trimmer. IF you are getting only 1 peak every turn, then you are either getting the best signal at max, or min capacitance - not good, because you may not actually be getting optimum, only as far as the trimmer goes. You would then have to add or subtract a turn or so from the coil for that trimmer. There are some cryptic marks on the green trimmers, but a nice arrow on the brown ones (in my kit) that are supposed to tell you which is which.
Info is in Carey's files, KX0R I think.
As far as the zero output - you did reconnect L3 after testing?
Also, listen in a receiver and see if there is actually a signal.
Good luck!

Double, tripple check the connections to the QSK switch fets between the filter and the mixer input. The gate of Q1 should be at 0 volts and the gate of Q2 5 volts. Make sure the connections of the LF3 coil are correctly installed and the wires are soldered properly.

Still looking for a built or unbuilt ATS-3B. Please email me with asking price. Thanks very much! Hopefully de Randy, K7RAN

2539. Pocket Digi 1.0.10 and the ATS3B (ver 3 firmware)

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-27 19:01:28 UTC
From: Full Some
Topic: 2539 Message: 2539

The following occur whether I use a simple or rail-to-rail op amp (LMC6462) interface with my laptop or desktop and fiddling with pre and post-ambles:

1. The ATS produces a very low level RF transmission (nothing showing on the power meter) in CW send mode when no text is typed. I get full output when I type characters but after they end I still observe the continuous low level RF transmission until I click the lightning bolt.
2. The CAT/frequency option produces some unusual results:
- if you put in the full number of digits for the frequency (e.g. 70720) the ATS will subsequently indicate a frequency (pressing the menu button) of 7200 (i.e. 7.7200 mhz) with significantly reduced band noise
. - any frequency change (e.g entering just 72) results in the ATS generating signals well off frequency although the ATS indicates a frequency of 0720 [i.e. 7.0720 mhz]. I first noticed this when testing into a dummy load with my BLT in tune mode. At 7.072.0 mhz, there was no SWR light; after entering 72 using the CAT function, transmissions lit the SWR light - pressing the menu button showed a frequency of 0720.

Has anyone noted similar observations? Does the CAT function work for you?

> I type characters but after they end I still observe the continuous low level
> RF transmission until I click the lightning bolt.

You hear DDS leaking out of the box even if PA is off. The leakage level is harmless, nothing to worry about. On TX, DDS output has the same frequency as RF output at the antenna.

> 2. The CAT/frequency option produces some unusual results:
> - if you put in the full number of digits for the frequency (e.g. 70720)

The frequency shall be entered in kHz: 7072.0, not 70720. The current ATS-3b firmware does not check band boundaries. It simply uses only three digits in front of decimal point and two digits after decimal point to set frequency. So you could enter 072 as well. It is already some weeks I wrote the firmware, I hope I gave you correct info.

> the ATS will subsequently indicate a frequency (pressing the menu button) of 7200
>
> (i.e. 7.7200 mhz) with significantly reduced band noise

The firmware will use the old MHz value - 7 and add hundreds of kHz - 720 to it, ending up at 7720kHz. This is certainly out of the narrow input filter, therefore reduced band noise.

Vojtich

Thank you for the information.

The DDS certainly puts out a very strong signal especially when coupled to the antenna.

The ATS 3b documentation indicated that a decimal point should not be used and I followed this. I just tried 7072.0 using the decimal point and it works and no strange harmonics! If I enter 072.0 (the zero doesn't show) the frequency read out is ok but the out of band harmonics return. Typing the full frequency change on the key pad in the program seems to be what is needed.

Thanks again..

From: jaakko330
Topic: 2542 Message: 2542

I put photos of my ATS3B to Flickr if anybody is interested

http://www.flickr.com/photos/oh7bf

Just finished the filter boards yesterday and made first QSO today.

First 0603 resistors were hand soldered, but then I bought Aoyue solder paste from http://www.eurogerd.com/ and a SMD rework station from an other address. I used too much paste for the first resistors, but learned quickly to use only thin layer on the pads. The filter board 0805 resistors are good for training. I started with resistors on top side and then bottom side. Then capacitors the same way. Next all the semiconductors except the DDS chip. Finally the DDS chip went ok, though I had to remove one solder bridge. I used a small racklet plate for preheating the board. Only one solder bridge under the display. The filter boards took some time with winding of the coils. Drilling holes to tin is problematic, should probably punch the holes with a suitable tool.

2543. building the B (and a small erratta)

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2007-12-28 23:25:19 UTC
From: ak3f
Topic: 2543 Message: 2543

finally some days off to build, so i worked on the 3B. got the whole thing done plus all the filter boards, except for two remaining toroids to wrap.

i used the cash's solder paste and an embossing tool for the smd work. i started with the dense side of the main board, and over a period of two days placed all smd parts held in place (barely) by the tiny drops of solder paste. i also placed all the surface mount semiconductors and ICs, including the DDS chip. rather than a lay a bead of paste down perpendicular to the pad as i have seen in the online demos, i put separate droplets of paste on each individual pad and then set the IC down into it. so from the start i had no paste bridging the pins of the IC. done this way i figured i would not have to rely on capillary action to clear the pins.

as somebody mentioned the stress level of doing this is high. one wrong move and you can be ruined. all the smd caps look the same to me. this was made all the more scary by all my housecats who are prone to jumping up on the work table to say hello.

i then heated the board on my candle warmer and flowed the solder paste with the embossing gun. you need to be careful ... the adhesion of the parts via such a tiny bit of solder paste is tenuous at best. and with my embosser (craft store type) you can blow them off the board.

by the way, it is easy to use too much solder paste. i learned this on a norcal dummy load. only a tiny amount of solder paste is required. my syringe appears to just barely been used. i have plenty for several more big projects. my paste is about 2 months old, and i have kept it in the fridge. i had no problems at all with clumping or dryness.

the flowing went perfect. after solder paste had all flowed, i unplugged the candle warmer and let the board cool down slowly for a couple minutes, then took it off the plate. i looked at every solder joint, and all but two joints on a couple resistors had failed to flow. so i spot worked them with the embosser without issues. no solder bridges, and no tombstones. it was really amazing.

i flipped the board over to the front, less dense side, and did the same thing. i also stuck the led display down. i propped the board up on the warmer plate with some pennies on the corners, and flowed the front of the board. the front came out perfect, and the parts did not fall off the back either.

i followed the checkout procedure in the manual (second run of 100) and found no issues. however, the manual has a couple typos:

under Check out and Calibration it says to check the voltage of the PA gates, Q6 to Q8. this should be Q7 to Q9.

and it also says to check the drain of Q4 and key some dahs... it should be Q6, the PA Keying transistor, not Q4. neither does Q4 have a big tab like Q6 so this is easy to catch.

my reference oscillator was about 84 hz too high, easily corrected during calibration. and when doing the local oscillator trim and BFO setting, i saw two humps in the passband. i think this has been reported before and it was very slight in any case.

so far everything has been perfect and i had to stop to rig a convenient antenna accessible from by workbench. all i have left is aligning the filter boards and i'm on the air with it!

i have two toroids left to do because two toroids apparently got crushed by the postal service and came as crumbs. the train wreck bent up one of the green trimmers too, but i salvaged it. this is sad since steve carefully marks the shipping bag DO NOT MACHINE PROCESS FRAGILE. and everything in the bag is padded really well.

i look at this project and remain absolutely amazed at steve's design, and the fact that i got it built without any issues whatsoever (heh, so far). this was my first big smd project. it was a lot easier than i thought it would be.

If the LO trim produces the audio beat note, then the DDS is producing the correct frequencies. It could be that your frequency counter isn't responding to the TP1 signal properly. Try measuring at the R16/C28 junction instead.

>via paddle. There is also no receive and no transmit (I sofar completed

I just created a new folder in the Photos section of this group titled "VE3WMB ATS3A" and I have placed three shots of my ATS3A, which is in an American Morse Equipment AA1 enclosure, rather than the "traditional" altoids tin.

I think it was Jess AE0CW that was interested seeing these.

I keep the rig in a Pelican 1010 microcase (also shown in these pictures) during transport to keep safe and dry during transport and it just fits.

The companion case for the band modules is an altoids tin lined with conductive foam (the stuff used for storing ICs) secured to the tin with a few dabs of hot glue.

Michael VE3WMB

P.S. Its still a bit early, but Happy New Year to all of you!

Subject: Re: [AT_Sprint] building the B (and a small erratta)

i'm done except for labeling. i put a photo in the photo area in the ak3f folder.

my gold brick 3B, qbsa and the slt tuner. everything works just great and just in time for SKN.

i'm using a wire in the trees about 134 ft long with a 66 ft counterpoise. so far works fb on 80 through 20.

i used a round hole for the window over the led on the 3b. easier than making a square hole.

for drilling the thin tin, i first made a block of 3/4"hardwood that fit snugly in the altoids tin. with rock solid inside support on all sides, drilling was controlled and pretty easy.

2562. W1MT's calib procedure

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-01 14:29:00 UTC
From: kc7fys
Topic: 2562 Message: 2562

Cogent to the forum and not to bandwidth-hogging:

ATS3 Calibration Procedure

Almost everyone has a computer and receiver these days. This calibration procedure requires a receiver capable of receiving WWV at 10MHz and a computer to receive the audio. Using Spectrogram, Spectran, baudline or equivalent you can calibrate the frequency and offset pretty accurately. A noise generator can be helpful or just a noisy band.

Prestep: Peak the IF transformer for peak noise. (Use noise generator if you have one or just a wire connected to the antenna connection. This is for the ATS-3 only)

Step 1: Tweak the trimmer cap on the ATS main board to position the filter shape to where you want it. (Generally centered around 600Hz and a noise generator helps). Do this with the audio from the ATS rig connected to the computer and spectro program.

Step 2: Connect the receiver audio out to the computer audio in and start up your spectro program (free shareware version of Spectrogram 5.17 available at www.n0ss.net). Tune the receiver to 10MHz WWV and set the carrier of WWV to 600Hz (606.8Hz is the actual sidetone on ATS rigs with my firmware) on the spectro display. A general coverage receiver works FB!

Step 3: Put the ATS rig in calibration mode "CF". With a short wire (3"-12") on the appropriate test point (TP1) you should see a signal on the computer screen. Click the tune up/down buttons till the new signal matches the WWV carrier. In CF mode the rig will broadcast a near 10MHz signal from TP1. If your receiver is unshielded or is fed by a non-coax fed antenna, your receiver should pickup the tone broadcast via TP1. With the up/down buttons on the ATS rig, superimpose TP1's signal on top of the previously set tone of WWV. Do not power down the ATS rig, but go to the next step.

Step 4: With power still on, connect the ATS rig audio out to the computer audio in and click the menu button to activate CO mode. Move up/down buttons to center the tone on the previously chosen frequancy. Once tone is centered click menu and you are done. You can easily tell what freq to use by keeping your ATS audio connected to the computer and letting the rig send audio (click menu once so that the freq is announced). The screen will tell you what sidetone the rig is using.

Now your freq is spot on and your offset is such that if you hear a station at 600Hz you will be right on top of them (zerobeat).

FAQ

Is peaking at PIN 1 while in CO mode necessary?

You will notice that the peak for Pin 1 in CO mode is very broad and I would rather my offset match my sidetone to make zero beating easier than be perfectly peaked. Use the BFO trimmer cap to center the bandpass filter on your sidetone of interest using baudline or Spectrogram (Step 1).

2563. 3b ref oscillator/calibration question

Date: 2008-01-01 17:47:09 UTC
From: Michael Harnage
Topic: 2563 Message: 2564

You can remove power to "cancel". If you want to
adjust one parameter then you must adjust both. Just
remember the numbers for future reference... I use a
notation like -11/+3 which means tune down 11 clicks
for CF adjustment and tune up 3 clicks for CO
adjustment.

Hope this helps.

Yes. Default values are loaded when CF mode is initiated. This ensures a
known good starting point in case the calibration values get corrupted.

2567. Winding 75 turns of #30 on a T37-2

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-02 10:29:26 UTC
From: kc7fys
Topic: 2567 Message: 2567

A new potential ham here at Chez 7J1AWL brings more indoor time, and much more workbench tinker-time. Whoo hoo.
I've been poring over KX0R's Filter Module pdf and photos. Thanks for the complete information on these mods! However, how the heck did you fit 75 turns of #30 wire on a T37-2?! I've got 50-some crammed on there, and that's it. Your photo, although fairly hi-resolution, doesn't show how you fit that amount of wire on there.
Mine so far:
<http://farm3.static.flickr.com/2329/2157292339_d4555b2eae.jpg>
Ain't no more gonna fit. ((I'll leave this mod until last. Your recommended specs for the 40 meter module worked wonderfully. My KD1JV power meter reads just under 4 watts feeding it 11VDC. The (a lot less accurate?) center LED on my T1 antenna tuner lights alone. Looks good.
Anyway, did you use fewer turns, a slenderer gauge of wire, or?
Jonathan

2568. problems with ats3b

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-02 13:57:35 UTC
From: dave3wave
Topic: 2568 Message: 2568

hi
I solderd my kit. I made the check according the handbook page 22.
It's all ok until power on. Power on: the message "8" appears. The
display shoes "A". The current is abt 30-40mA. Power off/power on: "F"
appears on the display. It seams the lower bar of the display doesn't
work (reading out the qrg). So the F means E. E is over current
detection. But why after power off and immediate power on? After
"wrong" power on the F appears. The current is in the same range.
After pressing Menu the display is clear. While pressing UP there is a
constant tone.
The voltage at tp1 is ok.
The voltage at PA gates are ok.
Plug in a paddle: do works as a straight key. I changed from
alternative key to normal key. Dot (or dash?) works - but very fast. I
cant change the speed.
After power on (with paddle) and the F appears I push Menu and then
the fas keying comes....
Voltage Q6 (PA keying transistor): ok

The voltages according page 26 are ok - except U6 and U7 (sorry I cant
measure U7. The pins are too narrow!!)

Voltage of u6 (no sign on display):
Pin1: 0V ok
Pin2: 3.5V ok
Pin3: 0V ok
Pin4: 0V ok
Pin5: 2.7V ok
Pin6: 2V suppose ok
Pin7: 3.5V ok
Pin8: 0.1V not ok
Pin9: 3.5V ok
Pin10: 3.5V ok
Pin11: 3.5V ok
Pin12: 3.5V ok
Pin13: 3.5V ok
Pin14: 3.5V ok
Pin15: 3.5V ok
Pin16: 3.5V ok
Pin17: 3.5V ok
Pin18: 3.5V ok
Pin19: 1.1V ok
Pin20: 3.5V ok
Pin21: 3.5V ok
Pin22: 3.5V ok

Pin23: 3.5V ok
Pin24: 0V ok
Pin25: 0V ok
Pin26: 3.5V ok
Pin27: 3.5V ok
Pin28: 3.5V ok

Are the numbers of U8 in the schematics identical to the pin numbers of the IC? Pin 4 must have a short contact to the gates of q7/8/9. I measure a resistance of abt 9.5MOhm. That's a little bit strange.....

Have you any good ideas??

Jonathan,

Your question is a good one - I should have put that in my notes in the pdf. Maybe I'll edit it. You're the first to ask, so maybe no one else has looked at that toroid so far.

That LF4 toroid really is 75 turns on a T37-2. The turns are overlapped - just keep winding over the first layer. This is usually not recommended for best Q, but it works OK. It's likely that the toroid wound with overlap will have a much higher Q than the molded part we're replacing. LF4 is in the receiver front end, and it's not critical - in fact, the molded inductor will work OK, even with a slight mistuning, because 80M is a noisy band and we won't notice a few db of signal loss in the receiver. If you have some smaller wire and enough patience, you could use that - 75 turns will still be close.

Your target is about 22 uH, if you have a way to measure that inductor.

Another easy option here is to use the original 18 uH molded inductor and install a capacitor in the holes for C7F. C7F is not used in Steve's list of parts, but the board is laid out for it. I'm guessing that we would need somewhere between 10 and 22 pf for C7F to pull that resonance down, so CT1 will tune it right on, if we use the original 18 uH part.

If you get this inductor right, you should see or hear two peaks as you rotate CT1 through a full 360 degree turn. If you're "on the edge", or off-center, you'll only see one peak.

I tuned my filters at about 3.560 Mhz. Now that the 80M phone band goes down to 3.600, we have little reason to use this rig much above 3.600.

Let me know how you finish this and how it works - surprised no one else has asked...

Glad you found improvement on 40M with my suggested changes.

Jonathan,

I also used KX0R's filter. I ran out of space with 50 turns so I just overlapped the original windings with a second. layer and it worked fine.

I was concerned about stray capacitance so I checked the inductance and self resonant frequency with my N2PK VNA. The inductance measures 24uh at 3.5 Mhz so I removed 5 turns to get 22uh at 3.5 Mhz.

The adjustments went up went according to the directions and I was able to get 5watts out on all bands at 12 volts.

I spent the holiday time off building and operating this rig. I manually soldered the compoments and all went well. I had some difficulty visually verfiying the solder connection with the 0603 caps because the pads were not long enough; the solder connection is under the component.

I thank Steve for the tremendous effort he put into designing this rig and look forward to his future creations.

73,

Mike N2MS

For Pin 8 check that the cap (C40) is not shorted.
(With no key connected.)

Display: For pins 11-18, check them when the display should read "8". Only one should read 3.5V (decimal point), the rest should be nr 0V. Double check all solder joints on the MPU (Pins 11-18) and the resistors (R27-R34) and even the solder joints on the LED display.

Hi Mike
tnx for the short reply. C40 is not shorted (I measured it with a multi meter. The resisance dropped down to abt. 110kOhm. Shorted means for me a resistance <1 Ohm).I checked (resoldered) the display, mpu and r27-34: no success....
Which pin of the display is for the lowest horizontal bar?

I believe it is pin 16 (port 3.5). Try following the
voltages from there to the led. Without led display
and with led = "8".

Hi Mike
Bingo - the problem with the display is solved. It was pin2 of the
display. There was a bad solderpoint.
Now, power off and again on, "E" appears on the display. What can be
the reason for this point?

Dave,
Here is Steve's fix for this, posted on 9/19/07 -

72 - john - n0hj

A 22K resistor arcoss the 3.5 V supply is enough of a load to eliminate the "E" coming on with short power down/power up cycles. A good place to tack a 22K resistor is at the clock osc, from pins 4 to 2 or 1 to 2.

Dave,

For the power reset issue you can also just hold a
button or two down for a couple of seconds to drain
the buildup in the caps. Does the same thing as adding
the 22K resistor.

For your paddle, I still suspect the cap. But first
try reflowing the dash pin on the MPU. If that fails
to fix remove the cap to groud off that pin and see
what voltage you have at the dash pin of the MPU.

One more thought. If you have a jack connected for the
key try removing it from the equation. If there is a
short in the jack you will see thing like your getting
on the dash pin, too.

Topic: 2568 Message: 2582

First, the E problem.

There is not enough current draw to discharge the cap across the 3.5V regulator quickly, so when doing a quick power on/off/on cycle, the data used to tell if there is a "cold" or "warm" boot doesn't get corrupted. This is only a problem if there is no or a 80M band module installed. The fix is to either hold two switches closed for a couple of seconds after power up or to tack a 22K ohm resistor across the 3.5 V regualor (putting it across the C58 pins on the bottom of the board is a good place)

As for the other problems, they are likely caused by bad/missing solder connections. The steady tone is generally a bad missing connection somewhere in the audio amplifier section, the missing segment could be the cpu pin which drives it, the series resistor or connection to the display. Only working in straight key mode indicates a short on the dash input or a bad connection to the 47K pull up resistor to that cpu pin.

Hi Mike
I took the jack away -> no success.
I measured the resitance between pin 8 and ground. It was 1.9 MOhm.
There is no short between pin 8 and ground (between pin 9 and ground
is abt. 1.5 MOhm).

All,

Oops. I refered to the 0603 size parts as capacitors. They're resistors.

Miike N2MS

---------- Original message ----------
From: mstangelo@...

Jonathan,

I also used KX0R's filter. I ran out of space with 50 turns so I just overlapped the original windings with a second. layer and it worked fine.

I was concerned about stray capacitance so I checked the inductance and self resonant frequency with my N2PK VNA. The inductance measures 24uh at 3.5 Mhz so I removed 5 turns to get 22uh at 3.5 Mhz.

The adjustments went up went according to the directions and I was able to get 5watts out on all bands at 12 volts.

I spent the holiday time off building and operating this rig. I manually soldered the compoments and all went well. I had some difficulty visually verfiying the solder connection with the 0603 caps because the pads were not long enough; the solder connection is under the component.

I thank Steve for the tremendous effort he put into designing this rig and look forward to his future creations.

73,

Mike N2MS

You could try reflashing the program into the MPU.
Steve detailed a nice simple way to do it with nothing
more that some resistors and cabling. Search the
archive for a description. But I think there is still
soemthing else wrong. Can you take a closeup detailed
picture of this section of the board and post it
somewhere? Or send direct to my email address?

If you use flux while building the board it may be
worth while to clean the board. I have use a soft
toothbrush with acetone with success. Got to be
careful with some of the plastic parts though. :) The
smt parts can handle it though.

What is your power supply? If it's a 9v rectangular
battery try something with a little more ooomph and
see what happens.

Check the pull up resistor to that pin. Bad connection to the pull up resistor and you won't have the 3.5V on the pin! You should measure 47K to the 3.5 V supply to pin 8 of the MPU. If you don't then there is no connection to the resistor!

Hi Steve
The pull up resistor is R43 - correct? Between pin2 and pin7 of u6 I
have exactly 47kOhm. R43 seems to be ok.

Hi Mike
I cleaned the board with acetone. I took 12V dc: always the same
situation: pin8 0.3-0.5V and pin9 3.5V.

2591. Repair ATS3a

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-03 11:39:25 UTC
From: dj3kk.fred
Topic: 2591 Message: 2591

I was told by a friend that his ATS3a always started in
straight-key-mode whether any paddle or key was connected or not.
There was no ELBUG-function.
The voltage at P2.0 (dash) showed less than 1.6Volt, decreasing
the pull-up resistor showed no effect, reprogramming with the JTAG
interface was no help, too. P2.0 did not operate in high input mode.
So I decided to cut off the F1121A and solder a new one. Programming
it offered a new problem : all morse announcements ended with 2 dots
eg :w = s, 3 = 5, m = i, ect. so it was not possible to understand the
announcement. I thought about 2 possibilities to avoid the fault.
I could solder and try another new chip or I could try to modify
the source-code - for me the simplest way
(tnx Steve for publishing the code). After some simulation
it became obvious that there was a failure when reading out
register r14. So I replaced r14 by r6 and defined
a ramcell for r6 (&r6rp = r6) . After reprogramming the ATS3a with
the modified code it became alive with all functions as before.

Hi Ron,
The embosser works well, and with a soft touch, you can keep from blowing things around. The cup warmer routine works well, for preheating and making the additional heat less directed from the embossing or heat gun. The full heat gun is rather more than I would be comfortable with, too much uncontrolled air flow. For nearly the price of an ATIII, you can obtain a SMT rework station, they provide hot air, and controlled flow is easy, the soldering tips are pretty nearly the correct size, considering these are built for pros to work with smt boards. For the AT build, I am enjoying playing with an embossing wand. For the serious stuff, I will take it to the bench and work it with the rework station. That includes any of the parts that give a hint that the paste won't hold 'em. I prefer to work 'em once, rather than spend the rest of the day wishing I had. However, one trick that I use, sometimes... is the addition of a large... no make that a huge bowl that I work the paste on the board to heat with air flow. I've found that once in a while... the little critters grow wings... and even tho they don't have a taste for Red Bull, them wings will carry them right off the board.. and drop into the bowl. No diggin around on the floor. Yes, it is a bit unhandy to reach over the edge... tiny price to pay for instead of the alternative... I figure.
Good Luck, --... ...--Dale - WC7S in Wy

I got a Madell 850B on ebay a year or so ago for <$100. It is great! The small nozzle allows you to do one part at a time, if you wish. The air flow and temperature are front-panel controlled. I don't mess with hot plates, drink warmers, etc. I set 5-10 parts in the little dabs of solder paste, then apply heat from the Madell, I have a formica top on my workbench, so I don't even bother with a metal plate any more. Fast, easy and no messing around. My ATS-3B worked first time around, the first of my ATS rigs to do so.

I used a new Madell QK857, not cheap though. With the air flow set to half maximum I did not have any problems with the parts moving. I did preheat the board to about 100-140 C and used coins as spacers on the corners. Just do not put too much solder paste on the pads. I checked the amount of paste before heating under magnifying glass and removed extra with a tooth pick. After first soldering it is easy the add small amount of paste with a tooth pick, preheat and use the hot air tool to melt the paste. Even solder sucking wick works with the hot air to remove extra solder. For me about 235 C air temperature worked fine with the lead free paste. This is at upper limit of the specifications for the paste. After some practice it is probably good idea to do all the resistors and then capacitors on each side. Then semiconductors the same way and finally the through hole parts.

Holy Cripes!

You mean you can do a few parts at a time if you
want to? I got one of those too off of ebay and
didn't know how it would work. Sitting out in the
garage.
Been waiting for a block of time so I could set all
the parts of the ATS-3B at once then go at it.
If it is possible to set a few parts and use the
Mandell to solder them and then do another block of
parts at another time, that would help me out alot.

I just do a few at a time, mainly because I bump them off the pads too easily.
With the Madell it is no problem. You could even do 1 at a time.

Hi Mike
I measured the resistanc over R39 and got abt. 2 MOhm (instead of
47kOhm!). The resitor is labled with 473 - that's ok. I took R39 away
and it seams R39 is dead. I have no 47kOhm-smd-resistor here. I tried
it with a normal one.... no chance.
I'll look tomorrow for a new one

You may download the modified ATS-3a source code from pocketdigi.sourceforge.net and use windiff to compare the original Steve's version and mine. My code is mostly extension of Steve's one and I mostly replaced constants by defines, so it shall be easy to decipher the magic numbers.

I spent my holidays working through the KXoR filter module mods. I didn't get the results he did, but 5.2 watts on the 17M and nearly that on the 20M module made me happy. Actually, I don't know if I trust any wattmeter in my shack. Everything's calibrated off of something else that wasn't calibrated in the first place kind of thing. Anyway, question: I noticed in the flickr ATS photo group some modules wound loosely, some wound tightly. KX0R seemed to wind pretty close to the toroid, which requires a good strong tug on each turn to snug up the wire. Myself, I like to make the windings hug the toroid closely--but what's accepted as the best practice? I see some where the wire is slinky-like around the toroid--a very loose fit. I wouldn't be comfortable with that myself. But I am far from knowledgeable on the subject.
How are yours wound?

Hi gang.

I released PocketDigi 1.0.11 at http://pocketdigi.sourceforge.net. There are following new features implemented: RSID, PSK63F, PSK125, sampling rate conversion, tx delay/tx tail/ats3 preamble/postamble settings, keyboard accelerators, Handheld PC 2000 improvements, Waterfall FFT optimization and basic Smartphone support.

RSID is the famous Reed Solomon ID of Patrick Lindecker F6CTE. Patrick added this feature into his MultiPSK software year ago. Until now only MultiPSK (and since last week also Cesco's FDMDV?) implemented this feature. Instead of CW ID or Image ID, a sequence of 15 MFSK tones is sent at the beginning of every TX to identify mode and center of frequency of the following data stream. RSID has very high redundancy, so if the RSID is decoded with zero or one error, there is extremely low probability of false detection. The feature is very handy to automatically detect mode and submode of rare modes and therefore encourages experimentation. Also it is easy to tune MFSK16 mode as no tuning is needed at all. I found RSID very useful with ATS-3b transceiver, at it has only narrow not very flat CW filter. Even if the whole digital signal does not fit into the filter, if the mode has high enough redundancy and is strong enough, it will be still decoded if tuned properly. But without seeing the whole spectrum of the signal on waterfall, it is very difficult to tune it. With RSID receive on, one only needs to get the RSID signal into receiver passband to make sure the signal will be tuned correctly.

PSK63F is a nice mode invented by Nino Porcino IZ8BLY. It is a crossbreed between MFSK16 and PSK63. It uses convolution code and varicode of MFSK16, but for hardware layer it uses binary phase shifting at 63.125Bd. PSK63F tries to fight ionospheric flutter by faster phase modulation and forward error correction. It is well known that BPSK31 does not survive polar flutter. BPSK63 is better, but one loses 3dB. For DX work, PSK63F could gain back that 3dB and still show lower sensitivity for polar flutter.

PSK125 is nothing more than 2x faster, 2x wider and 3dB less sensitive BPSK than PSK63.

I finally added sample rate conversion. It took me a bit longer, because it is done in fixed point arithmetic again to make it computationally feasible on Windows CE devices. I have good experience with my iPaq 3630 and Jornada 720, they show very little clock error. But my new laptop shows as high as 4% error on TX and 2% on RX. Even PSK31 did not work at that level of clock error.

With the release of ATS-3b kit by Steve KD1JV, I received reports about having trouble to get the communication interface working. ATS-3b is controlled by Manchester modulation generated by sound card, which is translated to digital levels by a simple slicer. Some sound cards generate ugly transient response at the start and end of sound. I added four new parameters to control the shape of transient response: TX delay, TX tail, ATS3 preamble and ATS3 postamble. The first two are silence intervals. The next two are intervals of Manchester idle tone. The idle tone is shaped by raised cosine function now to minimize clicks, if it is longer than 50msec. Also Jornada 720 generates some ugly click about 200msec after sound output opening. I was not able to find out the cause, but setting TX

delay to 250ms either avoids the click or at least shifts the modulation after the click.

I added keyboard accelerators for accessing menu from keyboard. According to Microsoft GUI guidelines for Pocket PC platform, one shall not use keyboard accelerators. They work on my device though, so I leave them there. Menu pops up at Alt-T for tools, Alt-M for Modem, Alt-A for mAcros etc. F1-F12 execute macros on desktop.

Until now, I relied on testing of Handheld PC 2000 build by Helge Tefts. Last month I bought Jornada 720 on e-bay for whooping $40+shipping. I did some user interface improvements on that platform, made some missing features available like context menus on RX/TX windows etc. Jornada 720 has a two LiIon cell accu. I bet ATS-3b may be powered from the handheld's accu.

I replaced complex FFT by a real FFT for waterfall calculation, which lowers current consumption. Now all the DSP calculation uses less current than user interface updates + FEC and certainly less than backlight on my iPaq 3630. This is quite interesting. It shows that for HAM radio digital modems and PDA sized display, DSP CPU will be probably counter-productive as DSP is usually clumsy for general purpose computing. To improve current consumption even more, I would probably need to replace some stock user interface components from Microsoft like RX window by a custom one or get back to a custom design with very small monochrome display and simple user interface.

Ondra OK1CDJ bought himself a Smartphone HTC S710. The device does not have a touch screen and did not show menu in PocketDigi-1.0.10. Smartphone only accepts menu with two main level items. I modified PocketDigi to detect Smartphone and modify menu accordingly. There were some more changes to make it work on Smartphone. Here is a screenshot from Ondra running PocketDigi on Smartphone and FT817.
http://blog.ok1cdj.com/2008/01/ft-817-smartphone-digimdy-prvn-testy.html
In my opinion the non touch screen devices are more suitable for portable hamming as they are more rugged. Also Smartphones are designed for less energy consumption, often using smaller display, slower CPU, having integrated thumb keyboard and handsfree connector.

Ondra's Smartphone runs on Windows Mobile 6.0. He uses a tool to emulate mouse cursor to access tuning on the waterfall and to switch between RX/TX windows. I plan to improve usability to be able to tune by the D-pad. If you have a Windows Smartphone with WM5 and newer (no touch screen), please give it a try. I need feedback as I do not own any. I configured PayPal donations at pocketdigi.sourceforge.net. Please consider donating small amount. From the donations I will buy a Windows Smartphone to develop on.

If you have any problems with the software, if you have suggestions for improvement, please do not hesitate to send me an e-mail.

At the end of this e-mail is a list of changes since 1.0.10.

73, Vojtech OK1IAK

2007-01-01 Vojtech Bubnik <bubnikv@...>
* 1.0.11-pre4
- Added configuration of TX delay, TX tail, ATS3 preamble and ATS3 postamble
- Channels menu split to Channels and Modem to fit on 240 row screens.
- Handheld PC 2000 (Jornada 720 and others): Dialog boxes have OK and X
buttons on title bar now.
- Basic support for Windows Mobile 5.0 Smartphones with at least 240x240

screens.
You will still need a mouse emulator utility to control waterfall and switch between RX/TX windows.

2007-12-22 Vojtech Bubnik <bubnikv@...>
* 1.0.11-pre2
- Added RSID support. Thanks to Patrick Lindecker F6CTE for Delphi source and support.
- Default value of TX prefetch buffers set to 3 on behalf of user report.
- Sample rate correction finalized. Automatic sample rate detection based on user expereince with MultiPSK.
- Added menu accelerators. Very useful when using device with internal or external keyboard.
Alt-T: tools, Alt-C: channels, Alt-M: Modems, Alt-A: mAcros
- Added F1-F12 function key accelerators to execute macros and Ctrl-F1-F12 to edit macros.
- Handheld PC 2000 (Jornada 720 and others): Dialog windows are now centered on the screen.
- Handheld PC 2000 (Jornada 720 and others): Bugfix - menu is displayed again.
- Handheld PC 2000 (Jornada 720 and others): Context menu on RX/TX windows opens on Alt-Tap or double tap.
- Battery consumption improvement: Waterfall calculation optimized.

2007-11-18 Vojtech Bubnik <bubnikv@...>
* 1.0.11-pre
- Added PSK63F and PSK125 modes
- Mode dependent macros
- Sample rate correction library ported

>47kOhm!). The resitor is labled with 473 - that's ok. I took R39 away
>and it seams R39 is dead. I have no 47kOhm-smd-resistor here. I tried
>it with a normal one.... no chance.
>I'll look tomorrow for a new one

Send me a SASE and will replace the resistor. In the mean time, you can
tack in a 1/4 watt resistor, putting one end on the dash tap of the jack
and the other to any convenient place which has the 3.5V supply on it.
Value is not critical, anything between say 10K and 100K will work for now.

I share your comments about wattmeters. Measuring RF power accurately is not easy. The best tip I have is that the Norcal Dummy Load does a pretty good job of measuring voltage that you can use to figure your power. The load is very close to 50 ohms. My MFJ-259B said it was near-perfect at HF. My DVM, measuring at DC, agreed well. If your DVM is accurate, you will get good numbers from the Norcal load and the chart in the manual. I have several similar homemade loads with detectors, and they all agree pretty well at the 5W level.

I wind my toroids as tight as I can pull without hurting myself or the toroid. For thick wire, #22 or larger, I use smooth pliers to pull. The #26 in my ATS-3B modules is wound hand-tight - pliers are not necessary. Fred KT5X uses a pencil in a vise (tapered point-end) to hold the toroid, so it isn't held by hand. I learned to hold it in one hand and pull the wire with the other.

Another trick is to stretch your wire before winding it. This is to make it smooth and even. You just need to stretch it enough that is goes straight - no more. You can feel it. Magnet wire will stretch several percent before breaking, but you just need to pull firmly to make it straight. Obviously thin wire needs a very gentle pull, while #18 and larger require serious force using tools. Be careful not to damage the wire at a point of stress - normally I cut the wire back from a stress point, like where I had it in the vise or pliers.

Even with a tight wind, there will be enough looseness that the coils will be easy to adjust. The adjustments are part of how you get the band modules set up to improve power and/or efficiency. You need the

turns tight enough that they stay put when you spread them or move them closer. I suggest a dab or two of hot glue to secure the toroids when you're satisfied with your adjustments - otherwise just bumping them while handling could change the inductance enough to affect the match.

Commercially produced toroids are perfectly wound by incredible machines. If you see one of these machines in action, you will always feel weird winding toroids by hand. The machines wind them very tight.

There is some variation among the cores we use. Most of our powdered iron toroids are made ny Micrometals, although they may be sold by various distributors. There is good information at their website:

http://www.micrometals.com/index.html

The tolerances on Al for the type 2 and type 6 core material we use are +/- 5%. This means we possibly might see a variation of up to 10% in Al. I have some 20-year old Micrometals type 2 material that is a bit different from today's similar cores, but it's probably within 5 or 10%. The point is that even if you wind exactly like Steve Weber or me, you may not get exactly the same inductance. Also your capacitors have variations. Fortunately, adjusting the windings is pretty easy.

As said earlier, I think 5W is the safe maximum for a good adjustment, with a 12.0V supply measured key-down at the rig's power connector, before the protection diode (not the rig's own measurement, which will be less); and that's only if the adjustment doesn't cause too much current draw. Even at 5W the current protection may trip easily.

This all relates to the wattmeter error, because if your wattmeter reads 10% too low, you could end up adjusting your rig for too much current, or worse. I think Steve's suggestion of 4.5W at 12V is pretty wise for the masses, considering the various errors and how they stack up.

72 and happy winding...

Hi Steve
I got one from my qrl. Now it's ok. The paddles works perfectly! With
the correct schematics was it easy to find the problem. Tnx for the help.

From: David Packard
Topic: 2454 Message: 2617

Thanks for the description of the trimmer capacitors, Mike VE3EQP. This kit is an ATS-3a. My Bee kit is waiting for me to get this radio going! I was able to tune the filter boards for maximum receive sensitivity, but it is still low.

Steve, I checked Q1 and Q2. The gate of Q1 exhibits a voltage of 0, while that of Q2 is 3.5v dc. The latter reading is low. The solder joints look good. I reheated the joints of both devices, plus other solder joints in the area. When I rechecked the voltages, they had not changed.

I looked carefully at LF3 on the filter board (40m and 20m). It is difficult to see the wires entering the top side of the board, now that the in-line pins are there. Again, everything looks ok and I reheated the solder connections. I can't entirely eliminate the possibility that one or more of the magnet wires had too much coating remaining. Should I remove LF3 to be sure? Is there a way to check them while they are in-circuit?

Thank you VERY much for your assistance. 72/73, Dave K1YHR.

--- In AT_Sprint@yahoogroups.com, David Packard <dpackard@...> wrote:

Dave,

Do you have normal receiver performance on any band? Or do you have low sensitivity on every band?

If one band works OK, your main board is probably OK, and you need to look for problems on your weak-sounding filter modules

If all bands are affected similarly with the same low sensitivity, it's more likely your problem is on the main board. If so, study the schematic and PC board to locate the various connections in the input signal path. It's a little tricky with the two boards, three schematics, and various designators. For the ATS-3A your signal path on receive is:

1) From antenna jack, through L4, and to J1-7 on main board (MPU/DDS/TX CIRCUITS schematic)
2) To P7 on the PA filter board (Filter Board Schematic)
3) Through the Transmit Filter to P5 on filter board
4) To J1-5 on the main board and to the PA Output
5) Through C47 and T-R switch Q2 to J1-2 on the main board
6) Back to the filter board to P2
7) Through LF3 and the rest of the Receiver Filter to P1. Note that there are different circuits used for 80M & 20M and 40M & 30M in these filters for the ATS-3A. The signals still go to P1 for all bands.
8) To J1-1 on the main board, and to the Receiver Input (Rx IN, upper left, Receiver schematic). The receiver input is labelled J1-4 on the Receiver schematic, but that's an error - it's J1-1.
9) Pin 1 of First Mixer U1, SA612AD.
10) Through the rest of the receiver.

One possible area to look at is the T-R switch consisting of Q1 and Q2. These two 2N7002 mosfet switches work in inverse fashion - when one is on, the other is off. When receiving, Q1 is off, so it looks like an open circuit; and Q2 is on, so it conducts and passes the received signal through from the PA circuit to the receiver input via J1-2. So when receiving, we expect to see a "high" control voltage on the MUTE line to Q2's gate. This turns on Q2. But Q1 must be off, since otherwise it would short our received signals to ground; so we need a "low" signal on the T/R line to the gate of Q1.

For RECEIVE we should see:

Q1 gate low (near zero)
Q2 gate high (about 3.5V)

When transmitting, the control signals are reversed. We want Q2 to be off, so the strong signals from the PA don't go into the receiver. This means Q2's gate must be low. Likewise, Q1 is turned on, to short out transmit signal that leaks through Q2, so it's further reduced. When Q1 is on, its gate must be driven high.

For TRANSMIT we should see:

Q1 gate high (about 3.5V)
Q2 gate low (near zero)

The MUTE and T/R signals come from pins 20 and 16 of U6, MPS430. When MUTE is high, T/R is low, for receiving. For transmitting, the signals reverse.

It sounds like you checked these and they're OK. 3.5V is a "high" condition.

Since Q1 and Q2 are T/R switches, they don't have any DC levels on the sources or drains.

Hopefully you've been able to follow the received signal path through the schematics using my description above. If so, your next choice might be to follow the signal on the boards, using the same description, now that you understand what must happen. If you have a multimeter, you can verify the connections on the drawings. There aren't many DC levels to check in this path, so you can just check the path with the unit turned off.

Visually inspect ALL the connections in the receive path using a bright light and magnifier. Look for shorts as well as opens. If you think you have a poor connection, use a meter to verify it. The soldering of your toroid wires can often be verified with a meter, but it won't reveal a short across the coil.

I had a tiny solder bridge on one of my filter modules, across a coil, on the component side of the board, that reduced my receiver's sensitivity on one band. I didn't see it, until I did a bunch of tests and verified that there had to be a problem.

If you have a signal generator and scope, you could inject a signal and follow it around the receiver with the scope. If you do this, keep the level down, well below 0 dbm, to prevent damage to the first mixer. This kind of testing may locate a short or open in the path.

If you have a stable generator but no scope, you could inject a low-level signal into the receive path at various points, while you listen, perhaps revealing where your problem is.

While the receive circuit is hard to follow on paper, the way it works is not complicated once you get familiar with it. The header

pins and jacks are very reliable and not likely to cause an open circuit. The sensitivity of the receiver is excellent, once it's working right.

I'll echo Steve's comments that most problems found are related to soldering. Visual inspection is your best tool, but you have to try really hard - use very bright light, try it at different angles, and plenty of magnification. Others have used digital cameras to make high-rez closeups that reveal problems - try this if you're able to do it.

The JA hams in this YahooGroup know "ZA DAISO" stores well. It's the popular variation on the 'dollar store' concept. This metallic green paint was right off the shelf. I feel inspired to go back and start labeling my other various QRP junk I've built. Maybe an entirely green metallic station! It would look good on the hood of a '73 Plymouth Duster with one of those "airfoil" rear spoilers. I recommend using inkjet decals--that was JN1GLB's idea. His are clear, though.

Hi Jonathan,

The story on that tuner goes like this..

I sure like that Elecraft QRP auto tuner.. lets have a look at the schematic..
Hmmm. I think as an experiment I will build a switched inductor chain similar to that but with a slightly larger range and then add a variable cap and make a similar tuner (but non-auto). The only trouble is the capacictor. Look at these physically small 532pf caps on Ebay (Ebay Item number: 150085706358) Perfect!
Look at this cool web site that shows how you can efficiently load up nearly anything with a "T" tuner..
http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=3677
I think I will add another variable cap and make this thing a T tuner (now that I know the trick to make it work efficiently)
Add in a resistive bridge LED tuner.. .. done! and it weighs six ounces.
Only thing is I want a tuner that just weighs one ounce or less. so there will be another project.

Hey, I got a message from zl2tch@... off of the ATS Flickr photo pool. I've migrated many of the photos from the photos section here to that private pool for better viewing and commenting by members of the ATS group who do the Flickr Shuffle.
This shot: http://farm3.static.flickr.com/2112/2123238321_b20f57c842_o.jpg ...shows it clearly. It looks like a variation on the LWT tuner you can get from NorCal. No?

Thanks Gil!

This is an interesting, well-photographed video - shows lots of techniques and tools. It discusses flux and shows how it's used with wire solder in some interesting ways.

The video doesn't show solder paste or hot air assembly, so it's worth looking at Cash Olsen's site for the demo of hot air soldering using paste.

The more we know, the more we can do.

2634. Different ATS3? And mine!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-11 03:06:22 UTC
From: kb8dns
Topic: 2634 Message: 2634

Hi All!

I built my ATS3 in March of 2005 and it worked FB right
off! My construction techniques followed most of the suggestions I
found on the web and some I came up with, couple of them are kind of
unique!
A cheap brownie pan was the best and part trays were
used and keep everything in order. I used a lighted magnifier lamp and
reading glasses and checked over my work with an old camera lens. I
also found that binoculars, backwards help! Ground everything was my
goal even to the point of boiling water in the house to prevent dry
air, drank lots of tea then!
My special tricks.... I used a 5 watt grounded
soldering pencil from RS, flattening the tip with small pliers and
shaping to a wedge point with a file. Holding the parts in place was
the real challenge! You're going to laugh at this.... I held them in
place with a long finger nail and touched the iron to the soldier and
then to the part, YES even to the SMD ICs! The only parts that gave me
trouble were the SMD resistors. I checked each and every soldered part
with a magnifier before proceeding. About three six hour stints and
the main board was done. Another two to three hours on the band
boards, I have yet to finish the 30 meter band.
Just a few on the air contacts and several cross mode
QSOs but I have listened all over with the rig! I even sent an A
(didah) on 1955 at lowest power and very brief, beautiful reception on
my Icom 746 in CW mode! Skipped the receiver all the way down to the
AM broadcast band and the upper limit is about 17 meters.
I cannot say enough about Steve's kit! I missed out on
the B model but will look forward to the next! Now about the different
ATS.... ATS3-A!?

http://www.sovtechcorp.com/sovereign_3_024.htm

Not sure about this but seems to be a tracking
transmitter of some sort, post 911? cargo containers?

2635. KX0R Portable Operation

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-11 06:53:36 UTC
From: radio_kx0r
Topic: 2635 Message: 2635

All,

KX0R may be on the air this weekend from an alpine site at 11,700' in the Colorado mountains. It's "maybe" because of uncertainties related to weather and whether our group actually reaches the hut.

My antenna will be modest at best, but the site is awesome, on the side of a high mountain near the Divide, right at treeline. If I get on, I plan to be near 7.045, 10.120, 14.065 - depending on the contest and what's available. I may jump into the contest also.

Most likely time to find me will be on 40M, around 9 PM MST Saturday night (0400 UT Sunday), or later. Saturday afternoon is another possibility - between 2 and 5 PM MST, or 2100-2400 UT Saturday. Unfortunately I can't be more specific, being part of a group of folks, and subject to many of Murphy's laws.

No promises here - just maybe. I know the rig will work if I can get an antenna up and have no other problems....

I will use my name George for CW -
72,

George Carey Fuller
KX0R

Good Luck Carey!
I'd be curious which hut you're XC skiing (or snow shoeing?) into?
I'll listen for you but I think were to close for 40m and above?
Maybe 80m? but antennas for 80m are a hassle in snowy conditions! Have
FUN!

Cheers, Steve/n0tu

You could advertise your activation on the SOTA web page http://www.sotawatch.org/ though the summit probably does not have any SOTA reference yet. Here in EU we have a few good cw operators chasing the weak signals buried in QRM. The frequencies are typically 7031 - 7033 kHz and 10116 - 10118 kHz.

You should find considerable activity on the bands. It sounds like you know about the North American QSO Party - this Saturday from 1800Z January 12 to 0600Z January 13, 2008. The maximum power level is 100 watts, so QRP stands a reasonable chance.

Good luck, and do join the fray of the NaQP.

Any QRPer should find NaQP and "interesting" experience.

As I was listening to some extremely powerful PSK signals on 7036.50 ish, I decided to change frequency using the CAT facility. If there was an extremely loud signal in the passband, the frequency change would not be successful. When the signal ceased or decreased in strength, a CAT frequency change was successful. The 600 hz audio must be strong enough to confuse the ATS 3B before the CAT signals are sent. Those must not be 5 watt signals as I had to turn the volume on the headphones quite low to reduce the pain.

Be a better friend, newshound, and know-it-all with Yahoo! Mobile. Try it now.

2641. First ATS-3B Contact!!

Date: 2008-01-12 23:06:36 UTC
From: Jim Fraser
Topic: 2641 Message: 2641

Made my first 3B contact this afternoon on 20m with N0NI in Iowa from the SF Bay Area. I was running 4 watts to a 20m Hamstick out on my apartment balcony through a BLT Tuner set with my Tenna Dipper. The 3B is still wired-up with temporary wires to the connectors and not in an enclosure, and was powered by my QBSA.

It was just a quick contest exchange, but it's still a contact! And I got in some practice with the Touch Keyer I am incorporating into my enclosure.

I also tried 17m and 30m with appropriate Hamsticks, but no luck. I could not get a good enough match with my 40m stick to try that band, the 3B immeidately displays 'E' when transmitting. So I might be out of luck trying to work 40m/80m from home.

Jim K6JF

Congrats Jim,
Exciting, isn't it.
I made my first CW contacts on mine today, I had made lots of psk31 contacts with my laptop and PocketDigi, but no one would answer my cq's in CW mode with the ATS3B. Leave it to the contesters. Luck would have it, my first QSO was to California, second to Florida and third to Washington state. I just knew the next would be to Maine, but no such luck.

Good luck,
Bill, ni5x.

2644. Re: Trouble with new ATS-3a

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-15 23:25:24 UTC
From: lownslow1601
Topic: 2454 Message: 2644

Last Saturday, I brought my ATS-3a, which has low receive sensitivity, to my friend, Keith WB2NVY. Keith is an EE who works on digitally-controlled power systems. The first thing that caught his attention was the short piece of RG-174 with a SO-239 at the end. We soon learned that between the connector and the center conductor pad on the board the resistance was significant and changed with manipulation of the coax. Changing the coax and connector produced a great sounding receiver. We promptly worked MN and TN during the NA QRP Party on 40m! The tx put out about 2.25 watts with a 9v battery. However, as we played with the radio, we found that moving the pc board could produce momentary loss of receiver sensitivity! After experimenting, we decided that this problem was caused by the plug size adapter I was using for my paddle. It was difficult to imagine, though, how the paddle could effect receive sensitivity.

The next morning, I hooked up the radio to the doublet I have at home and turned the radio on. My problem had returned and no amount of playing with the paddle connector, removing the paddle plug, or moving the pc board would help. I have made macrophotographs of each side of the board and I am systematically inspecting and reheating all solder connections. If this recheck does not help, I plan to bring the radio back to Keith's bench and trace signals through the receiver, as described by Carey KX0R.

72/73, Dave K1YHR.

I will agree here with Steve. I was dissatisfied with my initial effort at mounting the ATS3a in an Altoids tin (= ugly), so I decided to try again. The original mounting was a tight fit and I had trouble getting the board out. I discovered that the receiver had gone deaf. It turned out that one of the caps had cracked under pressure. I was able to track down the bad cap by injecting the antenna signal at different points in the circuit and then used a magnifier to find the bad part. After if was replaced, as was well again.

There's always a music tie-in. Hams have a lot of musical ability. Banjo fingerpicks would work.

This would be great for Pedestrian Mobile operations, the hose clamps
could easily be adjusted to fit over even heavy winter gloves!

I guess you could take this one step further and make a glove key; using
snaps or rivets attached to finger/thumb as the contacts and snaking a
couple of small insulated wires through the material of the glove.
Hmmm this gives me some ideas for the upcoming FYBO ;-)

2653. Yet another portable key invention - The "UD" key - hand held iambic key

Yahoo group: AT_Sprint (2002 — 2008)

Hello group,

The hose clamp keying method is indeed clever. I think I'll try it but with a slight twist. I'm fond of iambic keying so a hose clamp around the thumb, first and second fingers would allow for true iambic operation with just a little practice.

In the mean time - let me offer something I've invented and been using for many years now. It is a modified 35mm film canister with a couple of push buttons mounted at a 90 degree angle from each other. It's extremely light weight and allows for iambic keying while holding the unit in one hand. You can send iambically while walking, driving or huddled up inside your sleeping bag. In fact, I mostly use it on the trail while in my sleeping bag. With my earbuds in my ears and my UD key in my hand I can lie there with my eyes closed while sending / receiving CW and the other hikers nearby think I'm sleeping. They don't hear a thing (wide band receive allowed me to listen to my buddies in SSB while I sent them CW on 20 meters). This little key along with my ATS-3 also won the grand prize in 2005 at Trail Days in Damascus, VA. After explaining to the crowd that I built a portable ham radio that has allowed me to stay in touch with my friends all over the country while hiking the Appalachian Trail, they were somewhat amused. But when I pulled the Altoids tin out of my pocket and opened the lid to show the guts, chins began to fall to the floor. Thanks Steve. We owe it all to you.

By the way - UD stands for UP / DOWN (not to mention that it is part of my callsign). I got the idea while playing around with my Icom-706 while using the UP / DOWN buttons on the microphone to send CW.

Pictures to follow. I hope they transfer.

Very nice Gary! I'll have to try that idea. I'm planning on playing in the VHF test from a local mtn top this weekend weather permitting. Single handed keying would be a huge convenience not to mention be able to send with gloves on! I'll let you know how it goes.

Thanks for sharing! Steve/n0tu

wrote:

KX0R was on the air from the Sangree Froelicher hut last weekend.
Our group skiied and snowshoed the 3 miles and 1500 vertical feet to
the hut at 11,700 feet, located a few miles from Leadville, CO.

I used a piece of split firewood to throw a string into a tree - this
supported a compromise antenna best described as "85 feet out the
front of the hut and 33 feet out the back". Most of the antenna was
15 feet above the snow, and the highest point was the far end at 20
ft. It could be considered an off-center-fed dipole. The hut is on
a 30-degree slope, which probably favored signals to the east.

With 3-4 feet of powder snow everywhere, I had to wear snowshoes to
get the antenna up and down.

I used a modified ALT. I worked several NA Contest stations on 20M,
including PJ5NA, before moving to 30M to ragchew. 30M was nice just
before sunset, and I had a good long chat with WE0Q at Dent, MN.
Also worked N6VOH in CA, on the wrong side of the mountain, before
the band went long.

After supper I got on 40M - worked more than 20 NA Contest stations
in just over an hour, including WH6R (wrong side of the mountain) and
VP9/K7AR.

Before turning in, I decided to see if I could match 80M. Amazingly,
I loaded up with no problem, and quickly worked 8 contest stations,
including W1TO in MA, N3QE in MD, and K4GMH in VA. 80 was so nice I
wished I'd tried it earlier, before getting sleepy.

Key points:

1) No feedline was used
2) Antenna was a real compromise
3) I carried several pieces of #22 PVC wire so I could put up
whatever would fit the site
4) The EZNEC models for the antenna, done later, were medicocre,
several db worse than a dipole on all four bands - but they don't
include the sloping ground
5) Even though the antenna was low, it radiated well from the high
mountain with the deep valley below.
6) By using a series resistor with my 3-cell lithium battery, and
with an absorbtive bridge in my tuner, I was able to tune reactive
matches without tripping the ATS-3B overcurrent detector.
8) I operated for over 3 hours, including 1 hour of ragchewing, at 5W

output, and the lithium battery dropped from 12.6V to 11.75V.
9) The ATS-3B worked perfectly
10) All the radio stuff weighed 3 lb 5 oz. Over 1 lb of this is the
pack I use for an organizer. Room for improvement!
11) Compromise is the key to successful portable operation

Sorry I couldn't do more ragchewing, but the NA Contest dominated 20,
40, and 80M.

Fred,

Sangree's Hut is one of the Tenth Mountain Huts. "Hut" is too small
a word for this nice backcountry lodge.

It's about 5 miles NW of Mosquito Pass, and we could look up along
the summit of the Mosquito Range from the hut. The hut is about a
mile south of Buckeye Peak, just below treeline.

You can read more about this hut and others here:

http://www.huts.org/hut_details/belvedere_hut_details.html

The ATS rigs are perfect for this kind of trip, where weight is so
important.

Thanks for the cautionary notes, but I am a GENTLEman! I should have described more exactly what I meant by "move the board." With the board on the desktop and the coax end to the right and the paddle socket to the left, we slid a finger tip along the desk surface until it came in contact with the left corner of the board. Pushing a little with the finger tip was sufficient to produce rapid increases and decreases in receive sensitivity. That is probably why we began to suspect something in the region of the paddle connector. However, I have carried the radio in a small ZipLoc bag in my shirt pocket a couple of times to confer with some of my friends. I am not aware of putting pressure on the radio, but it is possible. Thanks for your interest and I will soon have reheated all of the solder connections. 72, Dave.

2666. Portable Tuner - Modified ALT

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-19 03:58:25 UTC
From: radio_kx0r
Topic: 2666 Message: 2666

I just posted a photo of my modified ALT. I started with Steve's design, looked at the SLT manual on Doug Hendricks's website, and built this. It evolved as it went.

This one will do the regular L-matches, with the caps on either end; or they can be on both ends for a limited PI network. The parts also can be configured for the two caps to be in series across the output of the L-C circuit, with the antenna connected to the tap between the caps. This provides a differential capacitor effect and is useful for fine-tuning a partial match. With the plain L-C circuit you have to hit the inductor right on the money to get a perfect match, and this gets harder on the higher frequencies, since you only have a few choices for L.

The caps are the Doug Hendricks polyvaricons, with about 210 pf total range.

I added a 16 uH inductor and a .25 uH coil to the original 5.

Additional jumpers allow extra capacitance to be added in parallel with the variables; and both or all these caps can be put in parallel across either end of the C-L or L-C. This enables some useful low-Z matches at lower frequencies. I even put in a jumper to allow use of just the 60 pf variable cap section - this could make for less-critical matches on 17 and 15 meters.

There also is a way to create several L-C-L T-networks, and these work OK for some loads.

This is a fun tuner if you like to try different antennas and frequencies. On the other hand, there are so many variables set by jumpers that the confusion factor is significant. Experience helps. It's very helpful to listen with the receiver to set up the initial configuration; then the LED bridge is used for the final match.

If you're going to use the same antenna and a couple of bands regularly, Steve's basic L-match may be all you need to stay on the air. At just over 4 ounces, including the box, leads, gator clips, and an RCA plug, my version weighs more than Steve's, so it's not really better, unless you want the options.

The best idea to come out of this is the one you don't see, because I haven't tried it yet: eliminate the tedious jumpers and use DIP switches. A unit with 7 or 8 DIP switches would control a set of inductors nicely in a logical, quick way. It would require less board space and would be more reliable - jumpers can be lost, and they break. Configurations could be set by DIP switches. They're low-cost, weigh

very little, and work nicely on perf board.

A nice C-L-C T-match could be built using the DIP switch idea for making the variable "L". I may try one of these next.

The flat "knobs" for the polyvaricons are made from red plastic, cut with a small saw and filed smooth. I drilled a center hole for a tight fit onto the cap shaft and added some epoxy to secure the "knobs". Make sure no glue gets into the capacitor.

Hopefully some of you will start with these ideas and come up with better tuners. A good tuner will let your ATS rig do its stuff in the field.

I say this, even though I think the BLT is the greatest thing since the 807...

Steve, N0TU, and I had thought about this issue as well but we may try DIP switches mounted in sockets - that way if we fry the switch it would be easy to replace. I am also looking for tiny pushbutton switches to use as well - I found one in an old toy my daughter had and it seems suitable for using in the bridge circuit (DPDT).

Steve,

I got the DIP switch idea because I have a nice sample kit from Grayhill. A salesman gave me this stuff years ago. Grayhill's switches are generally well-engineered, with full specs, but not the cheapest.

I just went into the Grayhill online catalog and found that the type 76 & 78 DIP switches I'm looking at here are rated for various SWITCHING currents of up to 150 mA at 30V for 2000 operations per switch.

However, the CARRY current is 5A with a rise of 20 degrees C.

Normally with our tuners we don't need to operate the switches with RF applied. I think 5A of carry current is enough for 5W, allowing for weird impedances, circulating current, etc. CW operating is usually intermittent duty. The 2000 operations seems to be based on switching live circuits - we might get more life in a tuner.

Here's the link to the catalog:

http://lgrws01.grayhill.com/web/images/ProductImages/Dip_Group.pdf

The specs for the 76 and 78 series are down on Page 14. Note also the materials: these switches all use a spring-loaded shorting ball. Ball and contacts are gold plated, etc.

Contact resistance is initially less than or equal to 30 mohm and it rises to 100 mohms at end of life. Eventually the gold plating wears away.

I don't think anyone is going to burn these DIP switches out with 5W, although some might eventually wear them out.

Now that I see the specs I'm getting more interested in building a DIP tuner.

I also have some type 79 linear action switches - these are like sliders, and would work to make a simple, compact variable inductor. They're on page 15 of the catalog - real tempting. Others have used rotary switches to do the same thing. The 79 units have a higher spec resistance than the DIP switches.

I haven't looked at other manufacturers' specs, because I've got this box of Grayhill stuff staring at me. It's likely some of the other

guys have specs similar to Grayhill.

I don't think the current rating of the DIP switches will be a
problem with quality parts, and they sure would be easier to adjust
than those jumpers.

Whether the losses are a problem can be determined by testing a tuner.
Whether to build a T-network or another L is the question. I really
want to modify the one I just built, but I don't think it's practical.

I'm optimistic about this idea.

More DIP switch info:

The Grayhill DIP switch design must be pretty good. My samples are
25 years old. Digikey sells the same part numbers now.

A good starting point is Grayhill 78B08T, Digikey GH7193-ND. This
has the extended actuators. It has 8 independent SPST switches.

That one costs $1.02 for one, less in quantity, and they have plenty
of stock.

The 76SB06 is another good one: rocker style, 6 switches.

Many other configurations are available. Digikey seems to have stock
of most of the common varieties. You only need the seals ("S" in
part number) if you're going to immerse them in solvents.

For some reason the 76 series rated at 5A carry current, but the 78
series is rated at 4A, according to Grayhill's specs in THEIR catalog.

The surface mount DIP switches seem to have higher contact
resistance - no reason to go there.

Nice to know that some of the good DIP parts aren't gone yet.

Topic: 2609 Message: 2671

The local "Save a lot" had some $20.00 Bluetooth headsets for sale, so I bought one. Was able to get my PDA to talk to it and works with the Pocketdigi program. At least sounds comes in and out of the headset to the program.

Audio level from the headset is pretty low and the mic is very sensitive, so looks like I will have to make an interface board to attenuate the audio to the mic input and square up the headphone output to input the data to the 3B. Be kinda neat if this works and have a wireless connection between the PDA and 3B!

Hi
I assembled today the 40m band module. So far so good. I connected an antenna. But there was no difference in the audio level. To trim ct2+3 had no effect. I emited a carrier by my normal transceiver with low power (1W) in a dummy load. I heard the carrier with the ats2b and I was able to trim ct2+3. Connect and disconnect has no effect to the audio level. I think that's not normal.....

Using DIP switches is a great idea. The jumpers work fine on the stock ALT but when in the field you have to be very careful not to lose them. I always bring a few spares just in case and so far I have been lucky.

What I discovered is that the recommended 51 ft wire will also match nicely on 80m with the stock ALT (as well as 40m/20m). Thirty meters is a bit more problematic with this wire length but if you coil up a foot or two of the 51 ft length then 30m will match just fine.
I normally use either 5 X 16ft radials (made from a length of 5 conductor computer ribbon cable) or a single 32 ft wire on the ground.

BTW the ALT makes a great little companion tuner for the ATS-3 rigs, especially since the rig always sees 50 ohms while in the tuner is in the tune position and the tuner itself fits into an altoids tin, so that combined with the ATS-3 itself makes for a pretty small station.

The January Run for the Bacon is tomorrow night!

Sunday night - January 20th from:
9 - 11 PM EST
8 - 10 PM CST
7 - 9 PM MST
6 - 8 PM PST

This is a 2 hour, fun filled, friendly QRP CW contest open to ALL radio amateurs. Membership in the Flying Pigs QRP ARCI is not required. For the scoop on the details, please go to:

http://www.gentzow.com/fpqrp/fpqrprun.php

Hope to catch you on the bands!

All,

I just ran 1.2A through one set of contacts on a Grayhill DIP switch. I measured about 12 mV across the switch, so the initial resistance is about 10 mohm (0.01 ohm). It didn't change after a minute or so ON. I removed the current, cycled the switch, and retested - about the same results.

I decided I'd hit the jackpot.

After some agony, I opened up my newly-built and very functional ALT. In order to fit in the DIP switch, I ripped out many of the jumper pins in the center of the perf board. These were all held by 5-minute epoxy on top, which fortunately was not as strong as the perf board.

I hate to wreck a project that I just finished and that has proved itself so well - but those little jumpers made me do it !!

There will still be a few jumpers for the basic configurations, but the inductors will be selected by the DIP switches.

Stay "tuned" !

2678. What are the differences between ATS-3 / 3A / 3B ?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-21 02:04:14 UTC
From: mantermeadows
Topic: 2678 Message: 2678

Has anyone put together a chart of all the features and specs of the ATS-3 series? I'm a builder/user of an ATS-3 and have been very happy with it's features and performance since early 2005. I'll have to admit to a little ignorance as to what all the other versions would give me and what I would lose. I've scanned through a couple hundred postings in this group (there's no way I'm going to read all 2600+ postings) and I'm at a loss to tally up all the differences. How's the circuit changed? What's different in the firmware? I understand that there is limited space for firmware so to add to it something else must go.

I recognize the advantage of being able to use PocketDigi with the 3B, which I would love to be able to do, so what do I have to give up? I don't want to lose my wideband receive capability as I use that feature a lot. Plus wideband would be great to have during PSK31 operation. If I could pick and choose on features within the firmware I'd probably give up CW memory.

Any thoughts?

Gary - KC8UD

> which I would love to be able to do, so what do I have to give up? I
> don't want to lose my wideband receive capability as I use that feature
> a lot. Plus wideband would be great to have during PSK31 operation.

You have ATS-3. It has 40MHz DDS clock.
ATS-3A has only improved RX/TX switching to handle HF broadcast strong signals better. It has the same controller as ATS-3. It has 50MHz DDS clock.
ATS-3B has microcontroller with 2x more program memory, built in digital modes capability, single digit display and better CW shaping. It has 60MHz DDS clock and higher bands.

I developed the first digital modes firmware on ATS-3a. I had to disable DFE and Iambic-B to squeeze the extensions into ATS-3A. Also the calibration functions were removed as they are needed only once. One needs to calibrate with the original firmware and then to upload the new one. You could download the firmware for A at http://pocketdigi.sourceforge.net . Steve merged my digital extensions to ATS-3B, so it is already there. As ATS-3B has more memory, none of the features need to be disabled.

In theory it shall be possible to use the modified ATS-3A on the non-A version. As I was only able to test the modified ATS-3A firmware on the -A version, I cannot be sure whether I didn't break the wideband receive function of non-A. You could test it. You need to configure the source code (enable wideband, set lower DDS clock) and recompile it.

wrote:

Gary,

The manuals for the ATS-II, ATS-3, ATS-3A, and ATS-3B are all
available in the FILES section of this site. I just spent a few
interesting minutes looking at the ATS-II manual - quite a lot has
changed, but the basic concepts are all there.

The "B" has an overcurrent detector and protects itself in case of a
current overload. It adds the 17M and 15M bands in addition to the
other 4.

The "B" uses a few mA more on receive, but in transmit mode it's very
efficient on the higher frequencies, at any allowed supply voltage.
The final has a better 74AC02 driver.

Some of the control functions have been re-arranged on the 4 buttons
on the "B" compared to the "A". Additional features have been added
to the buttons, including the ability to send code.

The "A" and "B" won't receive wideband.

I can't recall seeing a chart comparing the features. Maybe someone
will make one.

Steve Weber wrote a brief, interesting history of his rig several
weeks ago - you can find it with the SEARCH features here - it
answers some of your questions. Reading all the postings isn't
practical - but searching by keywords works well on this site.

Amazing rigs!

wrote:

My DIP-switch-tuned ALT exists. I managed to rework my ALT without
hurting it. The DIP switches seem a huge improvement over the former
jumpers. The tuning is much more intuitive, particularly if you're
comfortable with binary numbers.

I have 8 DIP switches. 7 are used for inductance (they replace the
shorting jumpers), permitting 0.25 uH up to almost 32 uH, with 7-bit
precision (1 part in 128); and the eighth switch is used to add 220
pf of capacitance to the output capacitor.

There are still a few jumpers used to set up several alternate
configurations and to add even more extra capacitance. If I rebuilt
this alt, I'd have one set of DIP switches for L and one for C.

With enough extra C you can easily match low-impedance loads.

I'll upload the photos now.

I've played with it on the MFJ-259B enough - tomorrow it goes on the
rig for a 5-watt test. It's still possible that with some loads it
could fail...maybe voltage will kill the DIPs, not current?

Looks promising tonight...

My DIP-switch-tuned ALT exists. I managed to rework my ALT without
hurting it. The DIP switches seem a huge improvement over the former
jumpers. The tuning is much more intuitive, particularly if you're
comfortable with binary numbers.

I have 8 DIP switches. 7 are used for inductance (they replace the
shorting jumpers), permitting 0.25 uH up to almost 32 uH, with 7-bit
precision (1 part in 128); and the eighth switch is used to add 220
pf of capacitance to the output capacitor.

There are still a few jumpers used to set up several alternate
configurations and to add even more extra capacitance. If I rebuilt
this alt, I'd have one set of DIP switches for L and one for C.

With enough extra C you can easily match low-impedance loads.

I'll upload the photos now.

I've played with it on the MFJ-259B enough - tomorrow it goes on the
rig for a 5-watt test. It's still possible that with some loads it
could fail...maybe voltage will kill the DIPs, not current?

Looks promising tonight...

wrote:

The DIP-ALT handled 5W with a match to a 5K resistor. This match
should deliver about 158V RMS to the 5K load, and it causes the
voltage across the components of the L-network to rise to similar
levels.

There were no problems. I tested matches on 80, 40, and 20M at 5W.
I ran all of them while sending dashes for 30 seconds or longer.
This was long enough to warm up the load. The inductors don't get
warm - not enough heat to feel - certainly losses are low. The
polyvaricon handled this OK.

The Grayhill DIP switches are rated to withstand 750V RMS initially,
and 500V RMS at end-of-life; this is both switch-to-switch and across
the open contacts. I think this is OK for any reasonable antenna
we're likely to use.

Of course, you could probably fry any little tuner if you try to load
a coathanger on 80M, or lose your load, for example.

2688. Palstar ZM30 vs. Micro908

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-25 06:45:30 UTC
From: kc7fys
Topic: 2688 Message: 2688

Hello ATS guys,
Off-list, could I get a reply or two... are these two Antenna Analyzers one and the same, but one is kit and the other is built/tested? A fella over on eham says this, and maybe it's common knowledge. I'm in the mood for something a bit more robust than my venerable Tenna Dipper, and those colorful Excel spreadsheet plots on antennae sure look cute. The MFJ gets mixed reviews, but generally quite good. Anyway, is the AmQRP and the Palstar the same beast? Off-list would probably be appropriate, unless you guys don't mind listening in.

2689. ATS-3B with HF packer amp.

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-26 21:41:44 UTC
From: Mike Marcoe
Topic: 2689 Message: 2689

I was just wondering if any one has tried their ATS-3B with the HF packer amp?
I set mine up with 9 volts into the ATS-3B, about 2.5 Watts out (max input for the amp) Everything worked well on 20, 30, and 40 meters, but I have had some problems with the over current protection on the ATS-3B kicking out on 15 and 17 meters.
I was just checking to see if anyone else has had a similar problem or if I need to look at my amps input.
I have made 3 contacts so far with the rig barefoot, and have shown it off to anyone who cared to look (and some who didn't). What a great little rig and kit.

Gang, Myself along with Rooster and Peanut are heading out for FYBO
this Friday!

We'll snow camp Friday night so we can get an early start for that
good chilly multiplier. We'll be on Friday PM of course testing out
antennas making sure all is ready for FYBO. Hope to catch you for a
freezing Q!

FYI- The 'boys" and I did a practice run this last Sunday by
activating the Polar Bear Club call sign " KB3QES" (soon to be W3PBC)
during a very WINDY day hike. You can read about it in the Pack Ice
Newsletter: http://www.polarbearqrp.org/PackIceNews.html
or here's a few pics from Sunday's Polar Bear hike:
http://picasaweb.google.com/n0tu.qrp/KB3QES/photo#s5160355678909047490
Also a video but it's little OT and not much QRP related:
http://youtube.com/goathiker

I will have enough parts to make a limited number of kits (23) in a week or so. I have a list of 25 or so guys who want one, so I need to contact these people first to see how many still do.

The reason for only 23 is that is how many 3.5 volt regulators I have. The rest are back ordered until the end of Febuary, and by the time I get them it will be well into or past the first week of March. The second week of March I am leaving for the AT and will not be back until the end of May or early June. (Hopefully - the mind is willing but will the body stand up to a 900 mile walk in the woods?)

2696. VE3DNL Marker Generator

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-01-31 02:02:32 UTC
From: kc7fys
Topic: 2696 Message: 2696

Howdy there. I'm scratching my head here, because I just may have failed at the World's Most Fail-proof QRP kit. This NorCal marker generator--am I using it right? Tuned my Kenwood rig to 3.900.000, applied fresh 9V battery, tiny 'antenna' of hookup wire in "5K" connection. I assume I should be hearing an audio tone either at 3.9Mhz or 1600AM as I read in the manual. Nothing. Bupkis! Very oddly, however, at 1600AM on the boombox here at work, I hear a buzzing with the marker generator within a foot of the receiver--powered or not powered (9V alkaline battery)--but this buzzing is stopped by touching pin 7 of the MC14060. That's with power or without--which I find odd. Could I have zapped the IC and destroyed it with static?

From: gi0xac
Topic: 2702 Message: 2702

I started to build the ATS3B (2nd run) last week.
Some of you guys may already have pointed this out but while cross-checking my work I noticed that the value of C41 on the circuit diagram (schematic) on page 29 of the manual is given as 0.1uF while on page 17 it forms part of the 3 yellow 1000p (0.001uf) pack which I received. I presume that C41 is actually 0.001uf and not 0.1uf.

C16 is also not marked as such but its location is depicted in red next to C15 on page 17.

2705. Question about 30 Meter Filter Board component C3F...is it 47p or 470p?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-02-01 13:47:19 UTC
From: laseraddict777
Topic: 2705 Message: 2705

Hello, Group--

I recently got my ATS-3B on the air, thanks to Steve. In soldering up the remaining filter board for 30 meters, C3F calls for a 47 p (47) small yellow mono cap. The only remaining component I have left is the 470 p (470). This part is not used anywhere else. Should I request the specified 47 p from Steve or should the 470 p (remaining part from the kit) be used?

Thanks for your help. Rick, WB3BIQ

You need a 47p for C3F. Measure it to make sure it is
470 and not 47.

Yeah, thats the right part. Sometimes they mark them 47 and sometimes 470.
If it were 471, that means its a 470 pfd cap.

Steve's right (as usual).

The C3F in my 30 meter module is marked 470, and it works real well.
You have the right cap.

There are several marking systems in use for capacitors, and most of
us have to measure some of them to decide what they really are. Part
values ending in zero, like this 470, are ambiguous, unless you know
what system the manufacturer uses.

Dipped mica caps are commonly marked both ways. 47J is 47 pf 5%, and
471 is 470 pf, but 470 could be either value - you have to measure
it.

Disc ceramic caps have similar confusing marking systems. Last year
I sorted several hundred caps into a parts cabinet, and I had to
measure many of them.

2712. RE-Programming original ATS-3 to allow digital modes

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-02-07 20:37:52 UTC
From: mantermeadows
Topic: 2712 Message: 2712

Here's one I need help with. I'm very fond of my ATS-3 mostly because it will allow me to turn off the narrow band filter and have wide band receive. I understand that the 3A and 3B have lost this functionality. I would like to be able to interface my Pocket PC and have use of digital modes via PocketDigi but am hesitant to switch to a 3B. Do some of you programmers think that there is room in the ATS-3 controller memory to write the routine for digital interfacing by perhaps leaving out the calibraton routine? I don't have a grasp on how much memory is needed for the digital mode routine nor do I have the hardware and in-depth programming experience to attempt the procedure.

In other words...can the digital mode be programmed into the ATS-3 and what would I have to lose to get it to fit in? Will the clock speed of the original ATS-3 controller handle the digital modes? Can anyone out there help with compliling and programming such a routine?

Thanks.
Gary - KC8UD

2713. Re: [AT_Sprint] RE-Programming original ATS-3 to allow digital modes

There's not a whole lot of difference between the programs in the 3 and 3A,
so adding the digital modes should be possible. And then it would work in
the ATS-2 also. I supose it should be done, but I don't have the time to
tackle it right now. Maybe after my hiking trip this spring.

Hi Gerry.

> Do some
> of you programmers think that there is room in the ATS-3 controller
> memory to write the routine for digital interfacing by perhaps leaving
> out the calibraton routine?

I already answered you this question. You will need to leave out calibration, DFE and probably some of following: Tune mode, Iambic B, Test message to check connection between PocketDigi and ATS3.

You will need to download ATS-3a source from pocketdigi.sourceforge.net
Enable/disable features you could miss by commenting out some defines. For example, to disable "morse paddle by up/down buttons", you need to change line
#define HAS_STEALTH
to
; #define HAS_STEALTH
The difference is the added semicolon at the start of the line.

I would say, you need to modify following lines:

enable wideband
#define HAS_WIDEBAND

disable the connection test message to leave some place for the wideband function
; #define HAS_UART_PLAY

Enable extrnal paddle. My latest ATS-3b used touch paddle connected in parallel to up/down buttons.
; #define HAS_TUNEUP_ON_DIT
#define HAS_EXTERNAL_PADDLE
; #define HAS_STEALTH

> I don't have a grasp on how much memory is
> needed for the digital mode routine

Run the compiler and it will tell you whether the memory is full or not. If it is full, you will need to disable some other ATS3 feature.

> Will the clock speed of
> the original ATS-3 controller handle the digital modes?

There are three clocks in ATS-3 series circuit:
DDS clock
32kHz watch clock
R/C oscillator inside the microcontroller.

You don't need to change the DDS clock constant in the source code, as it is only used during calibration. You have the correct value already in flash. The other clocks are the same between all ATS-3s.

Hi Gerry,

I forgott to stress two things regarding my ATS-3a digital firmware.

I cannot guarantee that it will work for you. I may have introduce some new errors when I added keying by up/down buttons and disabled keying by external paddle. After I modified my ATS-3a hardware, I had no way to test the firmware on the original hardware. I also cannot guarantee that the wideband function will still work on your ATS-3, as I cannot test it on the hardware. You are on your own. In worst case, you will lose some time. You could always program back the original ATS-3 firmware.

I know of one problem. The straight key does not work.

73, Vojtech OK1IAK

2721. Simple resistor interface

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-02-10 23:51:53 UTC
From: Mike Marcoe
Topic: 2721 Message: 2721

I tried to upgrade the firmware on my ATS-3B using the IAR software and the simple resistor interface with no luck. I get the error message "can not find target device" and the led display on the ATS goes to "E".
So I figured I would ask those who have hade success at doing this.

1. I their a set voltage that is needed for the supply to the ATS3 when programming? I was using 9 Volts

2. When selecting the device should I use "msp430f1121a" as per W1MT's directions or should I use "msp430f1232" which is the actual chip on the board?

Thanks
Mike - WB9OQB

2725. Latching Relays -- suggest make / model

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-02-13 02:40:23 UTC
From: eplerkeppler
Topic: 2725 Message: 2725

I thought I'd ask if anyone has a pet make/model latching relay they use and where to buy it.

My application will be a 9.6 volt battery for powering the switching coil, so anything 9.6 Volts or less for the switching power is fine. I can always put in a regulator to get down to 5 V or 3 or whatever.

The loads with be a few signal level loads then perhaps maybe one for as much as a 200 mA load at most.

I would like it to be smallish and maybe 15 dollars or less but let me know what you know about / like.

-- Charles McMurrough WC5MC

*I'm going to cross post this to a few other groups so my appologies if we are like minded and share more than one group.

Charles,

A good choice would be the latching relays used in the Elecraft T1
autotuner. They run on a 9V battery and work well.

Several are used in the T1 tuner. I just did a little sourcing work
for you:

The relay is made by NAIS.
The NAIS part number is AGN2104H.
The coil spec is 4.5V DC @ 22 mA.
The contacts are rated for 1A @ 30 VDC. They probably will handle
more voltage at less current also.

Digikey sells this part as 255-1857-ND.
Price is $3.70 ea in small quantity.
They have stock!

Mouser sells the same thing for $3.68.
They have stock also.

Looks like a winner to me....

Carey,

Yes thank you so much.

This looks to be just what I was looking for.

I found the spec sheet on this line of AGN (Panasonic) relays.

I'll get my amateur/non-engineer hands on some as soon as I can to
make sure I can do with them what I think/hope I can do.

Thank you for your time and excellent formatting of everything.

2729. ATS-3A For Sale

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-02-13 19:27:40 UTC
From: Andrew C. MacAllister
Topic: 2729 Message: 2729

Greetings AT Sprint Folks,

Ed Manuel N5EM wishes to sell his ATS-3A.

The kit is built along with one band board for 40M. The other band boards are not yet built. Ed did a great job building the kit. It looks good and works well. Ed is asking $100 via PayPal and will pay for shipping to any U.S. address. Included with the rig is a partially completed balsawood box, earbuds, the manual CD and all of the parts for the remaining band boards. If you are interested, please call Ed on the phone at 832-326-5416.

Please DO NOT send e-mail back to me! I am just passing on the info.

2730. ISO: Homebrewer on CD

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-02-14 06:41:07 UTC
From: kc7fys
Topic: 2730 Message: 2730

Howdy,
I'm not sure if it was on the ATS list per se, but I posted somewhere that I was looking for the AmQRP Homebrewer magazines on CD that were available in years of yore, but are no longer. I got a tiny bit of flak for asking for what was perceived as an unauthorized copy. As a clarification--I'd like to know if somebody has for sale their Homebrewer (or other?) Magazine(s) on CD--the authorized, legitimate original.
Contact me off-list if you do. kc7fys at yahoo dot com

I bought some from this guy (Ebay) See number 120096057860.

He also has other relays, check his store and do a search for relays.
http://stores.ebay.ca/Techno-Star. Lots of stuff, quick delivery, no
complaints from this end

2733. Run For The Bacon - Sunday Night

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-02-16 20:05:45 UTC
From: Larry Makoski W2LJ
Topic: 2733 Message: 2733

The February Run for the Bacon is tomorrow night; and this month there is a twist.

Sunday night - February 17th from:
9 - 11 PM EST
8 - 10 PM CST
7 - 9 PM MST
6 - 8 PM PST

This is a 2 hour, fun filled, friendly QRP CW contest open to ALL radio amateurs. Membership in the Flying Pigs QRP ARCI is not required. For the scoop on the details, please go to:

http://www.gentzow.com/fpqrp/fpqrprun.php

This month, in addition to the normal certificates, there WILL BE A 1ST PLACE PRIZE !!!! I was presented with a lovely Flying Pigs wrist watch; and this will be awarded to the top finisher in tomorrow night's contest! While membership in the Flying Pigs is not required to enter the contest, it IS required if you'd like to have a shot at winning this watch.

Please use the Autolog; and have your entry posted at no later than February 23rd.

Hope to catch you on the bands; and good luck to all!

73 de Larry W2LJ

Test message to check connection between PocketDigi and ATS3.

I'm new to this forum so I apologize if this was already discussed,
but how can a CW rig handle psk31 - I thought we need an SSB rig for that?

Is there a special PC program that can bypass the need to the SSB
circuitry? That would be great!

Eric

Hi Eric.

> I'm new to this forum so I apologize if this was already discussed,
> but how can a CW rig handle psk31 - I thought we need an SSB rig for that?

DDS used in ATS3 series allows instant changing of phase and frequency by a command word. You could very well modulate RTTY, MFSK16, Olivia modes just by sending frequency change commands to DDS. It is not that easy with PSK31/63. PSK31 has raised cosine amplitude envelope. The envelope has dual purpose: To eliminate keying clicks on phase change and to help with bit synchronization on RX side. The amplitude envelope is approximated by on/off CW keying on ATS-3a/b.

> Is there a special PC program that can bypass the need to the SSB
> circuitry? That would be great!

There is no change in HW needed for digital modes. The only SW that could work with ATS-3a/b is PocketDigi. It generates command stream, that the ATS-3b microcontroller understands and translates to CW on/off keying and DDS commands.

Yes, you could run PocketDigi on desktop or laptop with Windows 95 and newer, on Pocket PC 2002 and newer, on Handheld PC 2000 , on Smartphone with Windows Mobile 5 and newer. Port to Handheld PC Pro is on the way.

From: Mike Marcoe
Topic: 2721 Message: 2739

Problem is fixed!
I tried to update the firmware with a JTAG cable but was still having the same problems. I e-mailed W1MT to see if he could answer a few questions and while I was waiting for a response I went into the BIOS of the computer and found that my LPT1 port was set as PS/2 so I set it to ECC with auto DMA and rebooted the computer. Now it programs the rig with no problems. I am not sure why LPT1 was set to PS/2 but the IAR software sure didn't like it.
I would also like to thank Mike W1MT for his time in answering my questions.

John,

I built the simple resistor interface Steve describes in the following message to upgrade the firmware in my 3B:

http://groups.yahoo.com/group/AT_Sprint/message/1869

Some folks were having problems with this configuration and he later made this suggestion:

http://groups.yahoo.com/group/AT_Sprint/message/1884

I built this interface with the 220ohm resistor changes and it worked fine for me. The interface was very simple to build.

USB parallel converters only support printers. They will not allow programming the ATS-3 microcontroller.

If you have a desktop computer, the simplest and cheapest solution is to buy a parallel interface card. If you have a notebook with PCMCIA socket, you could buy a PCMCIA parallel adapter. Some of them are real parallel ports.

The last resort is this USB to parallel converter. It is open source design, but Henrik also sells finished devices.

2761. source for SIP headers and sockets

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-02-25 19:28:43 UTC
From: John Shadle
Topic: 2761 Message: 2761

Trying to find out if someone could provide a Mouser part number for the headers and sockets for connecting the main ATS-3B to its band boards.

Thanks.

John,

I recently ordered the SIP socket strip used on the 3B from Mouser and will email you the part number when I get home tonight. I used them on a small pc board for band module storage.

As for the SIP pins I had found them locally at a surplus electronics store.

That's correct, John. The DB25 with a few 220 ohm resistors and some pins shorted together for grounds, a piece of ribbon cable, and a SIP header.

Search for "Molex 2.54"

Mouser page 1371 for pins and 1368 for housings. This
for catalog 633.

< http://www.mouser.com/catalog/633/1371.pdf >

I generally buy the long sections and cut them to the
length that I need.

The chips are not PICs, but QT-113H. I have little doubts about it, even though the touchkeyer seller insists it is a custom programmed PIC. I even asked him directly and he repeats his truth. If it was a custom programmed PIC, then he will not need to file out the chip label. I built mine with two SMD QT-113H chips, that I bought from Farnell.

You did a fancy job, but the keyer is very insensitive, if you glue the electrodes directly to the tin. You found it already by trial and error. The capacitance of the electrodes against the tin is too high. It helps a lot to elevate them. I placed a piece of plastic ruler between the electrodes and tin.

You could find more info on electrodes and sensitivity in QT-113H datasheet.

It sounds like a slightly sensitive point with the maker, so I thank you for your informative response. I'll correct my notation. I'm hooked on this device after using it. I'll upload a video to YouTube soon--it works good, and the PCB substrate does provide at least 1MM of non-conductive material (as your plastic ruler solution suggests).

Thanks again for your constructive remarks,
Jonathan

I have the PCB material on top of 2mm ruler, so the electrodes are about 3mm above the ground. I tried the PCB itself, but it did not work for me. If you read the datasheet, putting electrode on top of ground is strongly discouraged.

That's what I thought. Well, for now I have fairly good results, but given the chance to do it over, I would definitely choose different material that's both thicker and has a heavier copper. Most likely I'd just use separate elements of copper and substrate. The dit is definitely not sensitive enough without licking my thumb.

My son sucks his thumb--I should ask for his advice.

Thanks as always Vojtich, for your frank assessment.

Jonathon,

I finally had a chance to check out the pics. Very
nice. I like the Jetson look! I think touch on the top
is a good way to go. One of my early Spartan Sprint
efforts had a mechanical key on the top as well.

Voj is correct about the chips in the touchkeyer, they
are the QT-113's. This was discussed a couple of years
ago on one of the boards. Don't think he'd loose any
sales on it -- just look at other kits -- all parts
specified etc. Doesn't make any sense to me that he
tries to obfuscate them.

Enjoy, it looks great.

>The chips are not PICs, but QT-113H. I have little doubts about it, even though the touchkeyer seller insists it is a custom programmed PIC. I even asked him directly and he repeats his truth.

I think I saw these at the NH hamfest last fall. At $99.00, I though they were a little pricey. There were two chips on the board I saw, both with the numbers rubbed off. I would assume one was the capacitive switch and the other a PIC keyer chip, as this was a stand alone keyer.

There is a way to make touch sensers using a uP. Basically, you time how long it takes to charge the touch capacitor up to the trigger point of the processor input pin. When you touch the plate, it takes longer to charge. I tried this out and it worked reasonably well, but was pretty sensitive to temperature changes. Trying to make it self calibrating got to be pretty involed, so I gave up on it.

i think both statements are correct but i base this on circumstantial evidence.

the pinout of the QT-113 is perfectly compatible with the pinout of a 12f683. it is entirely possible that quicktouch uses a pic to implement their design and has them custom marked.

Both chips are the same. There is one for the dit and
one for the dah.

There are other chips in the QT series that would
allow multiple inputs however they are slower and
possibly not suitable for the touchkeyer application.

Vojtech,

I don't know if you have any plans to do more work with Pocketdigi, but if so, would you consider adding the mode JT65A? This past weekend I worked a fellow in TX from CA and his last comment was "4W HB" (I was running 50w). For a 4 watt hombrew rig he had a weak but decent signal which I had no problem decoding with WSJT. The first thing that popped into mind was my 4w ATS-3B, thinking this weak signal mode would be suited for the ATS-3B.

Jonathan:

I too have a touch keyer integrated with my 3B, however mine is the P3SMD. I was also looking at placing the touch pads on top of the tin pencil box I will be using for an enclosure.

A question I have in my mind is would the vibrations from tapping on the enclosure affect the stability of the transmitter frequency? Have you listened to your signal on another receiver while tapping on the pads??

Embarrassing, but NO, I have not even done that. However, it seems very unlikely mechanical vibration as slight as that of my fingerpad touches could cause instability. That's a question for those more educated than I--but I'd guess it's highly unlikely when compared to the effects of say, temperature or something.
My question would be, is ANYTHING likely to cause transmitter frequency instability in a radio of this type?
Jonathan

Nothing I can think of. If you put the rig in the freezer and then put it in the hot sun, there would be a small drift in frequency as it warmed up. Possibly banging on the reference oscillator with a hammer could make the frequency jump around, at least until something broke!

> if so, would you consider adding the mode JT65A?

JT65 mode is quite complex. It is written in mix of C and Fortran. It would not be straightforward to port it to Pocket PC.

I have some objections for using JT65A on HF. The tone spacing is about 6Hz, which is too close, if the Ionosphere is instable. If you search archive of digitalradio@yahoogroups, you will find reports comparing JT65A on HF to slow Olivia. I would recommend you to try both Olivia and MFSK16 modes. Both of them are already implemented in PocketDigi and are supported by ATS-3b. Also RSID is supported by PocketDigi/ATS-3b, which will simplify mode detection and tuning. The only problem is narrow width of ATS-3b RX filter.

Hi Vojtech,

Thanks for the reponse and information on JT65A. Yes, I know that it is a slow mode which must be why the information passed in a QSO is minimal. It was just an idea.

I have run Olivia and MFSK16 on the big rig so I am familiar with these modes. I do plan to try out the digital modes PocketDigi has to offer as soon as I get my 3B into its enclosure.

I have noted a consistent 10hz of downward drift during the first 10 minutes. The transmitter was not keyed during this time The start off temperature is about 68 F.
During a recent exchange, from a cold start, I was informed of drift but I do not know how stable the other station's xcvr was.

I'm drilling out and stuffing a fresh Altoids tin. One of the traditional signals of Spring in our (sub)culture. I understand that there are cutters and dies in pro shops to make a flat (cogential?) place on a round hole--such as one would want to stop a BNC connector from rotating. How can this seemingly impossible feat be accomplished by the home hobbyist with a drill press? It's definitely not necessary, but wouldn't it be nice to have that type of hole? Any advice?
Jonathan

just did a few of those this weekend for another project but not in an altoids tin.

i drilled a hole the diameter of the flats then used a fine tooth rattail file to elongate the holes as necessary.

they don't need to be perfect since the circular flange on the bnc hides the uglies and the nut, lug, toothed washer do likewise inside.

You need a step drill ...Harbor Freight has 'em. Hmm, guess they
make some where on your side of the pond? They look like this:

Well, I don't think a rotating cutter of any kind can do this. I'm imagining there's a punch or shear of some kind. I have a Dremel, but I just wondered how those 'flatted holes' are made.

Jonathan,

I worried about this question before deciding to use an RCA jack. The BNC sometimes requires a lot of force and torque to unmate, and it's really ugly in the winter at low temperatures, when you'd rather not touch metal very much. I use my ATS rigs for winter camping, and the RCA is better.

What really pushed me was that I weighed the two connector sets on a postal scale. A BNC jack and plug together weigh about 1 ounce, while an RCA jack and plug weigh perhaps a third of an ounce. Go ahead and use the BNC if you like, but it's pretty heavy-duty on that thin Altoids box.

Here's how to tighten a BNC jack really tight so it doesn't come loose easily:

Use a toothed lock washer and hex nut on the inside of the box. A flatted hole is great if you can file it to fit (just start with a smaller round hole drilled with a step drill and file the shape you want - it's not difficult in thin metal). Otherwise just use a round hole. To tighten the jack, take just the outer body part from an old BNC plug, and mate it with your jack. Now take a pair of vise-grips and set them to fit and hold the BNC plug body. Tighten the hex nut on the jack with whatever wrench you can fit inside, while holding the front of the jack in place with the plug body held by the vise-grips. If you apply too much torque with the vise grips, you'll ruin the two alignment pins on the front of the BNC jack's outer conductor. After you ruin one, you'll know how tight to go. You can get them tight enough that they don't come loose, without damage, once you learn. Don't try to screw the whole jack into the nut using

the plug body, because that usually requires more torque than setting the nut behind the jack while holding the front steady.

I keep an old BNC plug body handy for this job - just keep it with the jacks. It's all bare brass from various encounters with the vise grips!

You can loctite the nut on the BNC jack also. The outer connection will still be OK.

Don't try to grab the front of a BNC jack with pliers - you'll bend it, mess up the alignment, and likely scratch your box/panel when you slip off.

If you use RCA jacks, go to Radio Shack - believe it or not, they have a superior RCA male - their # 274-319, pack of 4. It has a durable plastic strain relief/cover that screws on precisely. It doesn't pull off when you unmate the connectors. The weight of this plug is minimal. This is the one to use portable.

Steve Weber thought about it when he included that RCA jack in the kit. Even an extra ounce is heavy when you're going to carry it for miles and miles in the mountains. "Take care of the ounces and the pounds will take care of themselves." I think Colin Fletcher said that. RIP...and thanks Colin.

Excellent precis.
RCAs (pin jacks here in JA) might be my next chapter. I've used BNCs mostly because they seem more 'radio-ey' but RCAs seem just simpler.
Jonathan

2795. ATS3 antenna connectors

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-03-01 14:47:48 UTC
From: ve3wmb
Topic: 2794 Message: 2795

Another option besides RCA is to use a coaxial power jack/plug for the antenna connection.

I think that this was Steve KD1JV's idea, that he either posted to this group or some other. I would just make sure that if you go this route to ensure that it significantly different in size from your actual power connector on the rig, as you might not want to plug the DC supply into the front end of the rig ;-). This reminds me of the Ten-Tec Argonault 509 which has RCAs on the back pretty much for everything and required much care when hooking it up in low light conditions for the above reasons.

Cheers,

Michael VE3WMB

P.S. I have even thought about using TV cable F-type connectors but concluded that since the center-pin is actually the center conductor of the coax that this might not be a great a idea for a pack/field due to the fact that you could easily bend or damage it. I suppose one could keep the ends of the coax mated to a jack while in transit to prevent damage. Certainly these things are ubiquitous and cheap and decent quality ones are rated into the GHZ range.

Johnathan,

In one of my former jobs I had several sets of chasis punches on my test bench which were designed to punch holes of all shapes in metal. Some were just round, some were square or rectangle, others were partially round with a flat side. We purchased these sets at one of the local electronics supply stores for around $15 or $20 as I recall. They're fast and simple to use. All you need to do is drill a small pilot hole and then unscrew the chasis punch tool as it comes apart into two peices. One peice with the threaded bolt goes on the outside of the chasis and the other threaded half with the cutting edge goes inside. You tighten the bolt down with a small wrench until it pops right through the chasis creating a clean hole with no burs. Check some of the popular suppliers such as Digi-key in their tools section and you may find a set that includes the size you want.

If one has lots of money, there are special punches made for these things. Since I don't fit in that category, I use a combination of drill bits, and dremel attachments. They never come out real pretty, but they usually work. As someone else pointed out, the lips on the connectors and the washers cover up the "ugly". One nice thing about altoids tins is that if you mess one up, just get a fresh one out and start over. I have also used small wood chisels (make sure they are good and sharp) for rectangular holes in thin material by laying the surface to be cut flat on a board.

Punches to make the D-shaped holes that snugly mount BNC connectors exist,
but their cost cannot be justified for making just a few such holes.

If you will be mounting these connectors from time to time, it will be worth
your while to make a template that outlines the D-shaped hole. A neat job
can be done using a drill and small files in some aluminum metal stock.

Hold the completed template at the desired location and with the desired
orientation and then scribe the D-shape outline. Drilling and filing will
do a much neater job when you have a scribed outline.

I use some backing and drill a pilot hole first, then either a step drill (cheap at Harbor Freight Tools) or tapered reamer to gently widen the hole as necessary.

As far as keeping a BNC connector from turning...that's easy. Solder it to the Altoids tin. These tins take solder readily and are great for soldering Bulkhead Connectors and for use as a common ground

plane.

A nibbling tool will do just the opposite of what needs to be done. You don't want to cut away more metal after drilling a hole. Part of the hole needs to be closed up. I thought of that too but then I had to realize I was thinking in the wrong direction.

Steve,

Because of the thinness of the metal and the small size of the desired D-shaped hole, a nibbler is probably too big a tool to control easily. A carefully manipulated needle file will provide the delicate touch needed.

The round hole that is drilled initially (with the metal backed up with a piece of wood) should have a diameter that will be slightly less than the distance between the center of the desired flat side of the D and the periphery of the desired round side at 180 degrees opposite.

Use flat, square or triangular needle files to establish the desired length of the flat side.

Then use round (rat tail) files, choosing the maximum file diameter that will never touch the flat side, to complete the circular periphery of the hole.

It all works best if you have previously made a template and use that to scribe an accurate outline of the desired D-shaped hole.

Finally, and most importantly, it's fun to do. After the first one, your results should improve markedly.

For those in the group who may still be wanting to buy a ATS-3B, I have six (6) kits available for immediate shipping and could have more ready in about a week if that isn't enough. I'll be leaving for my spring hike on the AT about March 27th, so if you want one of these you must act quickly, otherwise wait until I get back in June.

That would increase the bulk of the charger. I found a nice tiny charger for a Bluetooth headset which works with the PDA - bearly. Most Hostels will give hikers a ride to the a local supermarket. If they are starved for electrical outlets, I could buy a three way AC plug there to donate to the place :-)

I figured out a way to attach the little solar charger to the top of my pack. I glued the barrel of a bic pen on either side of the solar charger case to run elastic cord through and then clip to tabs on the top pocket of the pack. Since the trees up on the ridge line don't leaf out until well into May, there is usually plenty of sun, if its not cloudy all day.

I hope to do about 1/2 of it, from the start of the trail on Springer Mt to Harpers Ferry. Thats assuming I can manage to average about 15 miles a day and not hurt myself!

>Any chance you're taking a radio?
>
Yes, but I may not carry it all the time. Will likely "bump" it ahead from time to time skipping some of the harder and longer streaches between town stops when more food has to be carried. Historically, I have not used the rig much on the trail. At the end of the day, I mostly just want to eat dinner and go to bed :-) I may try mostly doing PSK since I'll have the PDA. That might be easier then trying to bang out CW.

I have a trail journal going at www.trailjournals.com under the trail name Slo-go'en.

Bill,

First 6 emails saying their ready to buy. Your #7 so will have to wait
until I kit up a few more next week. I'm waiting on 1 part which is in
transit to complete more. It might be here tommorow, but more likely
Monday. In the mean time you can send a check for $190.00 to me at

Steven Weber
633 Champalin St
Berlin NH 03570

and your kit will be ready when your letter gets here.

Subject: [AT_Sprint] ATS-3B kits available for sale

For those in the group who may still be wanting to buy a ATS-3B, I have six (6) kits available for immediate shipping and could have more ready in about a week if that isn't enough. I'll be leaving for my spring hike on the AT about March 27th, so if you want one of these you must act quickly, otherwise wait until I get back in June.

I will sign up for one, Steve.

Having one soon would be good, but I am ready to wait for the June batch if it comes to that. Especially if you would think those would have any kind of refinements. Right now I am finishing up my K2 kit, which will keep me busy for the next few weeks.

Drop me a mail: kristinn1 (at) gmail.com if needed.

73 - and have fun on that trip! Kristinn, TF3KX

2818. Optivisor for SMD work

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-03-10 00:25:55 UTC
From: Steven Pituch
Topic: 2818 Message: 2818

Hi all,
I am getting ready to work on my ATS3b kit. I have plenty of experience with through hole assembly building my complete K2 over the years, but haven't had much SMD experience. My eyes are are getting really bad too.
I was thinking of buying an optivisor. I wonder what strength to get. I have not read too much on the Internet about using then for SMD work, or what size to get. They seem to be very popular with jewelry makers. I thought the DA-7 would be about right with a 6 inch working distance in front of the lenses and a 2.75X magnification, but wondering if anyone has any advice on this.
Thanks,
Steve, W2MY

The cheapo version for abt 8$ with the swing down compound lenses, work great.

Hi Steve,

Few years ago I bought a simple binocular 10X / 20X microscope in a local hobby shop for about $150 (probably Chinese or Indian). I mounted it through a plastic tray to prevent small items from flying away. I am 77 yrs and have to use strong reading glasses, but with this microscope I could effortlessly handsolder my ATS-3B without any faults. I used very thin 34 SWG solder wire, so I had to feed a length for each soldering. I recommend you to try some kind of microscope!

I'm curious about how normal perscription eyeglasses would work with various magnifiers? My left eye is much weaker than my right eye, so I either need a magnifier that can go over my glasses, or else one that has adjustable strengths in each eye. Does anyone have suggestions?

Eric

OK,
Thanks everyone for the input so far. My biggest question now is what strength of optivisor or mageyes do you people prefer for smt work.

I am thinking that getting an optivisor or Mageyes will need to be done via an Internet purchase. Hard to try on first. I did see that Harbor Freight also has a deluxe one for $10 that has 4 interchangeable lenses. Probably some distortion for that price, but I may try that one or the $5 one first.

Hi all,
Just found that the Joann sewing store on the Internet has Mageyes sets with the #2 and #4 lenses, or the #5 and #7 lenses. I will stop in today to the local store and see what they have. I have been cautioned about getting too much magnification but the one chip on the ATS3b board has a pretty fine pitch and am thinking the latter set would be better.

I only now have an old Nikon 7x loupe from my old view camera days, and a lighted magnifier lamp on a scissors boom from I think Office Depot. They are both nice but not really effective enough for the fine pitches. I have an old PCI card that I was using as a guinea pig and I really can't see close enough with these two devices.

I use the cheap one from Harbor Freight over my prescription glasses. They work very well, and they also have a flip-down higher power lens for when you need that extra magnification.

Hi Steve
Like you I had never worked with surface mount devices and my eyesight was not what it was! I purchased 3D binocular, magnifier (plastic and not very expensive) it has a 2.75 magnification and focuses at about 8" from the work. It fits over my glasses and by tilting my head I can either use my glasses or the magnifier. It worked absolutely fine and I got the 3b working first time.
I also had a small glass hand lens which I used in conjunction with the magnifier to read component values and to check and check again for solder bridges and correctly placed components.
My main problem was stopping the components sticking to the soldering iron tip. The best solution was to hold them down with my fingernail or a small pair of tweezers. Do work in tray to stop them from shooting onto the floor.
Best luck with the project. This is a super rig and I have had lots of contacts using 2W on 80m and 40m - the only bands open at the moment when I get home from work! At the moment I am using an 80m triangular loop and it does tend to overload a bit at night. I slightly detuned the 40m RF filter to remove the problem. I will probably have to re-peak it for portable operation. Maybe it won't be such a problem away from Europe with its powerful broadcast stations close to 40m

Hi all,
Thanks everyone for the input on the magnifiers available.

I went to Harbor freight as it was my first choice and they had nothing in stock.
I went to Joann Fabrics because that was my second choice as they advertized Mageyes, but they had nothing in stock.
I went to Hobby Lobby but they had nothing in stock.

I ended up at Altex Computer. They had various Optivisors. They let me try them on. I finally got the NA-7 (2.75X). It was on close out for $29.95. With the ICs on my test PCI card I brought along, it really seemed to be the best for me.

While I was at Altex I bought some fine desoldering braid and liquid solder.

I promised myself that I would finish my ARRL EC-003 training course before tackling the ATS3-b. I have 11 lessons to go. Let see how long it takes...

Hm. OK, well, while working on a sort of prototype of JN1GLB's Altoids PA (beta version of assembly manual and READ_ME in files section), I went to hook up my 3B and noticed something odd--no output.
My WM-2 needle will barely move on transmit (9.2V power in) on the most sensitive mW setting, and the computer part of it functions right, scrolling through functions and whatnot, keyer works and paddles work--but basically ZERO joy on transmit. It worked before and I was able to tweak up to about 4.7watts out on all bands.
Waaaa. What should I be checking first? Connections look good. If I'm not mistaken, a load mismatch would trip the protection circuit, right? So my finals wouldn't be toasted (how do I check that?)
Tips please,
Jonathan

Topic: 2835 Message: 2835

You know, before something happens.... you plan ahead, and are very aware of the possibilities, and even consider what you will do "IF" the something happens. All this pre-planning usually pays off.. however, during all this pre-planning, necessary and to some extent, optional, however much it may be, there is always that little... tiny... tingle.... in the back of your mind... that tells you.... somehow... somewhen... that it is pretty much impending, and without fail... will happen.
So... when it does... and that little 270 ohm SMT resistor leaves... in such a huff... offended, apparently by the inadvertant touch of the point of the tweezers, the sinking feeling in the pit of my stomoch, is overwhelmed by the gratification that... "No worry, plans have been made, it will be stopped by the edge of the large pan" So... after searching the pan.... with all the surrounding area, the sinking feeling returns... a bit stronger, this time, as the realization sinks in.. that the little resistor has, in its fit of irritation, "left the pan". So... plans have been thought through... and now, one must follow those plans.. for fear that the sinking feeling will swallow up the "pre-planning safety". Now... it is down, to the floor, cement, and no hiding places.... non.... not even a spec... (as seen from the "before" side). However.. as seen from the "the little critter got outta the barn - ad the door wasn't even open" side...there must be either 1. a secluded hiding place, or 2. the little feller was a lot wilder and untamed than ever expected.

So, after looking at a few places... I suppose it may be best to "suck it up" and order one....
Somehow.. it just seems rather outta the fence line.... that the wild, untamed sucker is 7 cents.... but the
total order is a 300 times that.... plus postage.

Maybe the best plan would be to insure that there are enough wild, untamed critters in the corral, to insure that there is one available for taming.. the next time?

So.... one of those large shippers, should be expecting a large order.... including at least of few of each color, size, and shape....
so much for pre-planning... no... wait. This is pre-planning... just a bit further over the next hill than usual.

hmmm... one wonders... if ropin one of them critters that has already been tamed, would pay off?
hmmmm.. at least they are tied up....

Sorry for the blank previous post. Seems if you double click "reply" the next screen has "send" there and off it goes.

In preparation for the creation of my ATS3b, I have procured a 12x24 inch static mat and I just bought a bare metal 105."x15.4" Enchilada pan (I guess thats what they call a cake pan in Texas). I am assuming that the anti-part-deflection-containment-vessel cake pan goes on top of the static mat. Any suggestions?
Thanks,
Steve, W2MY

Howdy,
Welp, after tooting my horn and being very reasonably and mildly warned by Vojtech about the use of the touch keyer on the Altoids tin directly, I need a tiny bit of advice. Despite the educated opinions of some, this configuration works quite well. Just one problem, though--I send 7J2... instead of 7J1... It seems to add a dit at inopportune times. Not good to have defective keying. This seems to happen above 15WPM only--so it leads me to believe I might be able to tweak capacitance on that pad and get a suitable response.
I actually don't know what I'm talking about in the sense that: do I want MORE or LESS sensitivity to get that odd extra dit outta there?
Any actual experiences would be appreciated.
Here's the video of what I'm talking about:

I also have some problems with additional dits at times. My touch pads are on a plastic box. I find that I have to concentrate more on my sending and just need to learn to be quicker getting the fingers up off the pads. I am so used to keeping my fingers on the paddle that it is a hard habit to break.

i played around with the horizontal surface tapper approach long enough to decide i didn't like it.

the problem is that your fingers always want to relax to the point that they fall on the sensing surfaces.

it does make for a nice integration however and probably is adequeate for short qsos after some practice.

i've now settled on more conventional vertical paddle arrangement but still with touch keying.

2845. RFTB - tonight!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-03-16 23:31:18 UTC
From: Larry Makoski W2LJ
Topic: 2845 Message: 2845

The March Run for the Bacon is tonight; and I apologize for the short notice! I just now realized today is the 3rd Sunday of the month!

Sunday night - March 16th from:
9 - 11 PM EDT
8 - 10 PM CDT
7 - 9 PM MDT
6 - 8 PM PDT

This is a 2 hour, fun filled, friendly QRP CW contest open to ALL radio amateurs. Membership in the Flying Pigs QRP ARCI is not required. For the scoop on the details, please go to:

http://www.gentzow.com/fpqrp/fpqrprun.php

This month, in addition to the normal certificates, there WILL BE A 1ST PLACE PRIZE !!!! This month's top place scorer (who has not qualified for winning a prize so far in 2008) will win a set of Flying Pigs coasters! You can quaff a few brews and prevent your beer glass/mug from damaging your table.

Please use the Autolog; and have your entry posted at no later than March 23rd.

Hope to catch you on the bands; and good luck to all!

Like you gentlemen have discovered, and I concur: the tapper is a nice addition to the ATS3B--but in my case, too, I still like working a paddle for some reason. Having the touch pads does add another option that I appreciate having.

Nice for demonstrating the rig to non-hams and just in case other options don't work out.
Jonathan

2848. NAQCC Sprint Wednesday night!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-03-18 01:13:29 UTC
From: Larry Makoski W2LJ
Topic: 2848 Message: 2848

This coming Wednesday evening will be the monthly NAQCC Sprint for March, 2008.

I will refer you to the proper URL:

http://www.arm-tek.net/~yoel//sprint200803.html

There you will find all the details as to time, frequencies, this month's Special Award, which will be dedcated to those of us who use indoor antennas

This is a monthly event that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate; but you must use QRP power levels to compete for awards.

Come join us and have a real good time!

73 de Larry W2LJ

Jonathan

A similar situation occurred with by ATS III -
everything worked but low output (less than 200mw). I
traced it down to my power supply (6 AAA NiMHi).
Although the voltage was just above 6v, there was not
enough amperage. Check your dc input re: voltage and
amperage. I assume that your previous 4.7 watts
output was at 12v and not 9.2v.

2851. Re: [AT_Sprint] Band Filter Question

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-03-19 17:48:42 UTC
From: Bill Miner
Topic: 2850 Message: 2851

I just received my ATS 3B kit from Steve. Believe it or not I took the time to read through the Assembly Manual BEFORE starting this project.

I am confused about some steps in the "Band filter test and adjustment" section: Step 3 says to remove the green trimmer caps from the bottom of the board and relocate to the top of the board. Why would they be installed on the bottom? And why would I want to move them? Is it necessary to mount them on the bottom for alignment and then move them to the top (component) side of the board after alignment?

Then in step 10, it talks about moving the coils to the top of the board. Is it because there is no other way to access the adjustments when the band filter is installed on the main board? It seems like the components are facing the main board and not accessible when the board is plugged in. Is this correct?

Does anyone have an idea for a better case then the Altoids? Something strong but light?

Any other hints or tips greatfully accepted.

Thanks & 73, Bill - K6WLM

Some of the kits went out with trimmer top access trimmer caps instead of bottom access caps. If you have bottom access caps install on top of board so that you can trim thru the hole in the bottom. If you can top access caps you can bend the tabs and install as if it were bottom access or do as the manual says.

Personally, I put the coils on the top and simply pull the whole board, adjust, reinstall the filter board. Repeat as necessary. Power can remain on, JUST DON'T TRANSMIT WHILE THE BOARD IS PULLED! :)

Cases: I've done about everything one can think of for cases and have come to the conclusion that this rig must live in an Altoids sized tin. Can of spray paint will liven it up if you prefer. Bout the only thing better is the aluminum case from < http://americanmorse.com/aa1.htm >, but it is heavier and more expensive.

2853. Almost ready to head out

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-03-19 20:11:30 UTC
From: Steven Weber
Topic: 2835 Message: 2853

Got almost everything ready to head out on the Appalachian Trial in a week or so for a 2 month, 1000 mile treck. (if all goes well) I'm shipping all my hiking gear down to my folks house in Florida, where I'll vist for a few days before heading up to Georga, so it better all be ready by tonight!No way am I trusting my pack to the airlines!

I just finished fitting a battery charge indicator into the little solar charger gizmo. I was going to use a MPS430F2013 chip, but for the life of me, could not figure out how to use the A/D converter in that part! They made it way too complicated to use. So, I ended up using an Atmel Tiny15L, which was much easier to configure.

I tired to interface a Bluetooth headset into my ATS-3B so could have wireless connection between the rig and PDA. It worked, but with the headset mounted inside the tin with the rig, the headset was causing all kinds of interferance to the Bee. I could make most of it go away by putting my fingure over the headset antenna, but in the end I decided it was more trouble than it was worth, extra battery consumption and all.

Then I figured out a way to mount a cheap earbud speaker over the mic in the PDA just by using some rubber bands to hold it in place. Then I clipped off the other ear bud and wired up a plug with the interface resistors and cap inside the plug barrel to plug into the PDA headphone jack. Finally, I mounted and wired up a sperate stereo jack inside the Bee tin for the PDA interface cable to plug into.

Because the earbud is tightly coupled to the mic input on the PDA, I reduced the audio level by putting a 51 ohm resistor in series with the earbud. This is still a little too much audio, but by plugging in another set of headphones into the Bee's headphone jack, that brings the level down to be just perfict. Plus I can hear whats going on. A side benifit of freeing up the headphone jack by adding a dedicated digital interface jack :-)

I'm hoping working PSK on the trail will be easier than Morse. I won't have to concentrate as much and most of the QSO can be set up as macros.

It is hard to say when or how often I will actually get on the air. There are too many variables. I have to tent when I want to operate, as there is too much activity going on in and around the shelters.

When I do get on, it will most likely be around local dusk. All the camp chores are done by then and then a few quick QSO's before it gets dark enough to go to sleep. I'll try to be in a place I can operate from for the Spartin Sprint on April 7th.

Finally, like last year, I will have an on line trail journal going at www.trailjournals.com under the trail name "Slo-go'en".

In the second run of -3B kits, I had to use top adjust trimmers as the bottom adjust were not available at the time. Apprently, they were switching the inventory to lead free types and I needed them right at the transission. The old ones were all gone and the new ones were still being made.

For this third run, the bottom adjust type were available again, so were used. I thought I removed all references to the top adjust ones in the run 3 manual, unless your not looking at the manual on the CD but an older one from the files section of this group. Since there can be suttle differences between the different runs of kits, you should always use the manual supplied with the kit you get. I'll double check the run 3 manual to see if I forgot to remove those top adjust trimmer references. (might be in the adjustment instructions).

Hi Paul
Hope you have fun building the kit.
Interested you weren't charged by customs. Mine had a sticker on with £4.39 for VAT and an £8.00 handling charge. Total £12.39. This all seems a bit hit and miss as I have bought kits for more from the USA with no charge.
Having plenty of contacts with mine on 80 and 40 in the evening when the bands have closed down.

--- In AT_Sprint@yahoogroups.com, Steven Weber <kd1jv@...> wrote:

Steve,

Just want to wish you lots of luck down south on the AT. I grew up in Knoxville, TN, and my first backpack was in the Smoky Mountains. I've spent maybe 10 or 12 days on the AT along the TN/NC border (yeasr ago). It's beautiful and hard. Up one mountain, down to a gap, and up another. Thousands of vertical feet - lots of it with few switchbacks. Awesome places - in many ways, wilder than out here.

Sooner or later you'll be thinking about bears and boars - hope they stay away from you. They used to have little signs right along the NC line that said "Bear Sanctuary"...

Don't forget to watch for copperheads and rattlers - the copperheads are hard to spot in the leaves if they lie still...plus lots of harmless snakes on the trails down there.

You're going on an amazing trip, whether you complete the 1000 miles or not. Everyone in this group should know that going more than a few days on the AT is a big deal...this is not car camping.

I've spent about 40 years out here in the West chuckling to myself about how much easier it is to go hiking and backpacking out here than back there. Enough said -

Hang in there, and wish you the best!

Remember the trillium - you will see many, and they may bring good luck. Lots of great radio sites along all those ridges!

Bill,

Since you have the correct trimmers, you just mount them all where they belong on the little band modules.

I spent some extra time working on mine - I have both the ATS-3A and ATS-3B rigs, and I set them both up for 5W at 12V.

I posted detailed instructions on some mods to optimize these modules, along with the pros and cons. They're in the FILES section of this group site. The stock rig needs a few tweaks to give 5W on every band, but it can do this. I use my -B for portable work at campsites and in the local forests, as well as at home, and I've had no problem running 5W. Usually I'll operate on several bands with one antenna.

My story: always use a tuner, use a tuner with an absorptive bridge, and use a current limiting resistor in series with the battery to limit current during tuneup. If you run 5W, you'll probably want to increase the current limit on the rig by about 10% to avoid tripping while running at full power.

The ATS-3B is an amazing radio. Its full capabilities are sleeping now, waiting for some solar activity to heat up the upper frequencies...

There's a lot of information on this site - use the search features to find posts on key topics. Many of us have posted stuff while we built our kits.

Good luck

Carey:

I'm planning to get one of the 3b kits when Steve returns from his hike. I'd plan to use 3 lithium ion (lithium polymer) cells in series, for 11.1 volts. Did you do a power check @ 11 volts? I know these things don't put out as much power at lower voltages as they do with 12 volts, but Li-ION or Li-Polymer have a much better power/weight ratio.

Right now I'm just curious.

I tweak mine to give abt 2w at 9v and 4.5w at 11.1v. I
too like the 3 cell lipo packs.

>Just want to wish you lots of luck down south on the AT.

Carey,

Thanks. This will be my 2nd or 3d time hiking these sections of trial, so getting pretty familer with them.

Most of the shelters in NC now have effective food bear bagging setups, so bears are not encountered very often anymore. The Smokies used to have some bad bear/boar problems, but these are much less today. Open dumps and tourists feeding bears are a thing of the past and there has been a boar erratication program going on for some time in the park. I'm planing on taking an alturnative route though the Smokies, going around through the lower valleys on the east side instead of up on the high ridge, so I might have more animal encounters than others. I've never been in that part of the park before, so it should be interesting.

Its still early enough in the season down south and the trail is high enough that snakes are not a problem either. Still too cold for them. I saw a lot of rattle snakes in PA on last years trip. Usually in the morning, laying across the trail in a patch of sun trying to warm up. I would simply step over them and they would pay me no heed.

Steve,

Thanks for the good news and update! You should have a great time. The east side of the Smokies should be interesting - I've never been in there - I know it's pretty wild.

Best of luck - hope some of us can contact you. Please comment in your trail journal if you're going to be working CW and when!

Thanks

2865. ATS-3A Filter Module Improvements

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-03-23 05:19:55 UTC
From: radio_kx0r
Topic: 2865 Message: 2865

After I built my ATS-3A some time ago, I made a few changes to the filter modules to get a little more power out. I run mostly on 3 lithium-ion cells near 12V, and I want - and get - 5W output at full charge. These changes have worked well, and I finally got around to documenting them today - "better late than never".

I posted the pdf document in the FILES section of this site. Another similar document (posted last year) describes my changes for the "B" - they're similar.

Late last year, after adjusting all the filter modules in my "B", I took another look at the receiver input tuned circuits in my "A" modules. I was able to fix a couple of situations where a trimmer was tuned at its limit (not peaked); I also improved the sensitivity on each band.

Some of you may want to look over this list of "what works for me". You can definitely make your rig a little hotter on both receive and transmit, once everything is tuned up just right. All this stuff is easy to do, unless your toroids are covered in epoxy! Please read my warnings and guidelines first! Steve's recommendations in the ATS-3A manual result in good, conservative performance, and there are risks in messing around with these delicate little filter modules. I've added comments for each band. Changes are shown in RED. Remember that you need to adjust your transmit toroids (LF1 and LF2) by compressing or stretching the windings each time you change a part of that tuned circuit. You may need several iterations to get things just right...go slow and be patient.

Don't try to get more than 5W output, even though you can. Use a tuner with a resistive bridge, and always run into a good match. Don't run on more than 12V. I've never blown the finals in my "A" or my "B", but we've been warned...

If anyone finds a problem here, please post it to the group, and I'll try to help.

2866. Altoids tins for sale

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-03-28 15:00:41 UTC
From: shadle
Topic: 2866 Message: 2866

I have a whole mess of Altoids tins for sale of various sizes and types. They are excess to my needs and frankly taking up a bit of space that is at a premium at this point in my life. Most are of the typical size that you would find at your local drug store/grocery; however, I do have one larger tin, a couple smaller tins, and a Sucrets tin or two.

There are over 40 tins (probably close to 45 or so). If you are interested in the entire set then I would be willing to part with them all gladly for $25 + shipping of your choice (Priority Mail, UPS, etc.).

Thanks for your attention.

Hello everyone,

I just joined this group and would like to introduce myself. My name is Paul Huff, N8XMS, and I live in Livonia, MI which is near Detroit. I operate about 99% QRP CW and probably enjoy building gear as much as using it. I have previously built a number or QRP rigs including a homebrew 40-meter transmitter, TenTec 1320, Wilderness SST-40, Elecraft K1 and KX1, Rockmite 30, Himite 17, and assorted accessories. I am hoping to build an ATS-3B once the next batch of kits becomes available. I'm a little nervous about all of the SMT but I built a NorCal SMT dummy load for practice and that turned out fine so I hope that I am ready for the ATS-3B. I will probably be calling on the collective wisdom of the group from time to time and thank all of you in advance for any advice and help that you can offer.

73,
Paul - N8XMS

--- In AT_Sprint@yahoogroups.com, "Paul Huff" <phuff@...> wrote:

Paul,

Welcome to the group! You're the right guy for the ATS-3B. Be sure to watch this site for a chance to order your kit. Right now Steve Weber is on an expedition on the southern AT. When he returns in two or three months, he may offer more ATS-3B kits - that's my understanding.

This kit will be a fun challenge for someone who has built so many interesting kits. Most of us have found that the SMT assembly isn't too hard.

As you may know, there are two general ways to do SMT assembly in a hobby setting. One method is to solder each part with a pointed soldering tip and small solder, one joint at a time. The other method is to place all the parts on the board using solder paste, tweezers, and a syringe, and then use a hot air tool to reflow the solder.

Many ATS rigs have been built with the first method, and they work just fine. I built my ATS-3A that way. When the ATS-3B came along, there were postings here about using Cash Olson's solder paste and the hot air reflow method shown on his website. Check this out if you haven't already seen it:

http://www.zianet.com/erg/SMT_Soldering.html

Be sure to view the movies.

There were other methods suggested, many of them crude - like toaster ovens. Many of us have used the Cash Olson method successfully, and the results look like they came from a contract assembly house.

This AT Sprint website here has some nice resources for you - in the PHOTOS section are many photos of ATS rigs, cases, accessories, etc. In the FILES section are documents, complete manuals, schematics, test data, and firmware code. If you sign up, you can share in this and contribute to the group.

I posted a bunch of stuff about the hot air method, and so did several others - we were "blown away" by this nice experience. If you use the SEARCH function for the postings here, you can easily go back and read whatever you want. The search feature makes it easy to find the many comments and suggestions we wrote when we were building our kits and sharing our challenges.

In particular, Steve Weber has posted some important, articulate messages related to particular issues - assembly as well as circuit behavior. There also is a lot of material about the digital mode capability of the "B" rig.

Right now this site is pretty dead, since most of us built our kits some time ago, and Steve's out on the trail. If Steve does another run of kits, there will be more activity here.

You can download the ATS-3B manual in the FILES here, if you don't already have it.

I think the ATS-3B is one of the most amazing ham radio kits ever sold. The rig does what it should. If you get a chance to take it out in the woods or camping somewhere, with a good antenna and your BLT, you'll find out that it's a real radio, designed mainly for small, lightweight performance. It can run on whatever bands are available, you can ragchew forever, and you can work DX.

Hope you have as much fun as we have had...

2869. Beverage warmer method and the two sided board??

Yahoo group: AT_Sprint (2002 — 2008)

From: James McKinley
Topic: 2869 Message: 2869

GM Carey,
I have to ask this agn as I'm sure it's been asked before. Can you do a board that has parts on both sides using the hot plate and air gun? It would seem that the parts would lay directly on the warmer and not the board. Would this be a problem and also change the sequence of parts placement during construction?

Thanks,
Jim WD4OJY

> a board that has parts on both sides using the hot plate and air gun?

Yes, you certainly can. I built my ATS-3B that way, as have many others.

Place all the parts on one side (I think I chose the less-populated
side), and cook that one.
(Note that the beverage warmer just makes the board warm -- less than
100 Celsius --
to reduce thermal shock as the embossing tool melts the solder. It
also allows the
board to cool more slowly.)

Then place the parts for the other side.
When cooking this side, you can space the board away from the beverage warmer.
I think I had soldered on the mounting spacers for this, but you could
just lay it on some
nuts. The parts on the bottom only get warm, not hot, because the hot
air doesn't reach them.
Even if their solder did melt, surface tension would hold the parts in
place (so even the
toaster-oven method can work, apparently).

It's a litltle nerve-wracking to have ~100 parts on the board just
held with wet solder paste.
I bumped a few one time, but it wasn't hard to put them back. Just
find a time where you can
concentrate on the job and get a whole side done, and keep the cat out
of the room!

Good luck,
-- Bill, AB1AV

--- In AT_Sprint@yahoogroups.com, "Bill Noyce" <WBNoyce@...> wrote:

Jim and Bill,

Bill covered this good question just fine. I hot-air-soldered both sides of my ATS-3B using a modified candle warmer for the preheat, and an embossing tool for the hot air. If you search for the phrases "candle warmer","hot air",and "embossing" on this site, you can find most of what's been written here earlier. The basic idea is that I used aluminum plates to expand the candle warmer's surface and even out the heat. The only problem with the alumimum plate is that it takes a long time to heat up. See my picture in the PHOTOS section here.

To lift the board with already-soldered parts slightly off the hot plate, I just put quarters under the corners. Nuts would be great also. The hot air embossing tool won't melt the solder joints of parts on the underside, as long as you don't have it too close for too long.

The toaster oven isn't a good tool for soldering, because you don't have the close control and visual feedback that you do when working with a hot air tool. It would be easy to overheat and damage the board with a toaster oven. It has a very high level of infrared radiation, which tends to overheat the darker parts, like your IC's. It's designed for toasting bread and cooking food quickly, not for reflow soldering. Remember that what you're trying to do is duplicate the thermal profile recommended for the solder paste, and a toaster oven holds the temperature too high for too long.

I had the same problem with bumping parts held on by paste that seemed to be drying out, and agree with everything Bill said. It's probably OK to use hot air to solder the board in sections - others have done this. Remember that you have to do a close inspection and correct any problems after you're done. Use small desoldering braid and a fine point iron to rework any joints that aren't right. This isn't as hard as it sounds. Remember when you first learned to solder?

I've wondered about this (granted I hand soldered my AT3B)...

Commercial reflow ovens are quite often IR, so that shouldn't be a problem. Likewise , toaster ovens have thermostats, so preheat should be quite doable. When it comes time to cool it off (after peak reflow temps are met....~240C) I'd think opening the oven door would serve as a fairly controllable cool down...certainly as or more controllable than with a hand held blower.

I know a lot of boards have been assembled with the hot plate and embosser, so I'm sure it works, but I still think there's some promise in the toaster oven method. :-)

I have to give a positive plug for the toaster oven
method. I have used the toaster oven with great
success. Found it very easy to watch the process thru
the window and control the temperature with the
thermostat. I actually think it is easier to follow
the paste profile with an oven than with the hot air
method. Biggest issue with toaster ovens is that the
air flow is generally not very good and you should
look for a model that has convection, for better air
flow and more even board temperature.

That all being said, I actually prefer the hot air
method as I don't like getting the oven out for a few
minutes of work. :) Much easier to get the hot air gun
out for short term usage.

Either way is useful and a valuable tool in the
homebrewer's SMT toolkit.

Mike,

Your positive experience clearly exceeds my negative attitude toward the toaster oven! The toaster oven I have here has no fan, has a simple on-off thermostat, and uses about 1500 watts when the elements are on. I think it would take much practice - trial and error - to do a good soldering job with this appliance. Even for cooking it's pretty unpredictable. Your oven is clearly superior. With so many models available, generalizing on a soldering process isn't practical. I'm wrong to be so broadly negative - that's based on what I have here.

I know that the commercial reflow ovens, whether IR or convection, work just great. They have sensors and processors to get the profiles just right. The operators generally have a lot of experience, and they work hard to achieve tight process control in order to maximize yields.

I believe that the hot air method generally results in less thermal shock to the components than the soldering iron method. What do you think?

I'm aware of several instances of large ceramic capacitors (MLC chip caps) that were thermally shocked, eventually leading to failures of commercial equipment shipped to customers. Those failures were on boards that were manually soldered with irons, one end at a time. The failures took months to develop. When the capacitors finally shorted, they sometimes took the traces off the boards, because they were on a 50V rail with several amperes available. A very expensive problem for all concerned...

Maybe there is nothing to worry about with small chip caps from good manufacturers? My ATS-3A was hand-soldered, and it still works fine. Has anyone here had a failed chip cap yet?

Chip caps have a much bigger issue with mechanical mistreatment (and it doesnt take much!). I'm a components engineer, and keeping designs free of large (1206 and larger) MLCCs that are near connectors, shear areas for depanelization, snap in fasteners, etc, is a constant battle. As you note, they make GREAT short circuits... when they do short.

2879. ATS3b Construction Pregress and Ques

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-02 15:15:29 UTC
From: Steven Pituch
Topic: 2869 Message: 2879

Hi all,
Just a few notes on my progress building the ATS3b. First, the Optivisor DA-7 (high magnification) I purchased by default has been quite good. My vision is quite poor. With my Varilux glasses I can't see close at all, but without them all I can see is the tip of my nose. The NA-7 is OK when used with my glasses, as is recommended. But when I use the NA-7 without my glasses the results are very nice. Yes, I am working about 3 inches from the circuit board, but when I need to see that 603 part, they are really nice. I was able to solder the U7 chip with a conical tip with no bridges first time, so something is working out.

My next question has to do with cleaning the board. I am using a lot of GC Liquid Soldering Flux. It was crusted onto everything. I have finished the caps, resistors and semi-conductors, and have cleaned the board twice using denatured alcohol and a flux brush and then tamping the board with paper towels. It is still a little bit dirty. Is there a spray or something that is more effective? Also I wonder if I can just wash it with some detergent and water. Thats why I haven't put the switches and LCD onto the board yet.

72,
Steve, W2MY

Hey Steve and the gang;

I use the Chemtronics flux pens... both the no-clean and the rosin based products. The flux goes where I want it and I can control the amounts I am using.

They also make decent flux remover pens too. I seldom find a need to use anything else for either fluxing or cleaning. Occasionally I will follow up the cleaning with some water or and alcohol rinse.

Very best regards;

Bob

2883. Reference Oscillator Frequency Calibration Procedure ATS3b

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-05 01:13:11 UTC
From: Steven Pituch
Topic: 2883 Message: 2883

Hi All,
I am not sure about how to do this procedure, using my transceiver.

"Reference Oscillator Frequency Calibration
This calibration is most easily done with an accurate frequency counter. If you do not have access to one, but do
have a rig with general coverage, good calibration and can tune to 10 MHz, then you can use that. If you can
connect up a PSK program or other audio spectrum analyzer software which can show you the audio frequency
of the signal from the rig's audio, this will help a lot. Set the rig to receive USB at 9.999,000 MHz. This will cause
a 1 kHz beat note when a 10.000,000 MHz signal is received. The PSK waterfall can be used to show you when
you have adjusted the DDS frequency to produce the exact 1 kHz beat note. A short pick up wire attached to a
piece of coax going to the rigs antenna jack and placed near the TP1 test point should pick up plenty of signal. If
you have no means of accurately measuring 10 MHz, skip through this procedure by clicking the MENU switch
after step 6 and go directly to the LO cal procedure."

I am guessing it has nothing to do with WWV. I was going to connect my TS-480 with its high stability txco to a dummy load and set it for 5 Watts at first. I will then connect the headphone jack of the ATS3b to the sound card input. I have already calibrated the sound card in MixW. Then I will wrap some wire around the coax going to the dummy load and put the other end of the wire near TP1. Then transmit into the dummy load with the TS-480 set to 9999.0 USB, and look at the results on my sound card.

Does this sound logical?
Steve, W2MY

Dale,

D1 is a schottky diode rated at 1A. The ATS-3A used the SS12, which is a 20V 1A diode. The ATS-3B uses either the SS12 or the SS13, which is rated at 30V 1A. The schematic says SS13, and the parts list says SS12. Either one will work fine unless you exceed 20V reversed - if you think you need 30V of reverse protection, use the SS13.

Mouser has them both:

SS12 Mouser 821-SS12 $.20 ea Taiwan Semiconductor
SS12 Mouser 512-SS12 $.27 ea Fairchild

SS13 Mouser 821-SS13 $.20 ea Taiwan Semiconductor
SS13 Mouser 512-SS13 $.27 ea Fairchild

Pick one - they have lots of other choices as well.

I don't think Mouser has a minimum order, but you might want to order some other goodies while you're there. I just ordered a lifetime supply of banana plugs and jacks from them, and my online order was perfect and delivered in 3 days by UPS ground. I put bananas on all my balanced lines, tuners, and antennas so everything can plug together easily.

Sorry I don't have any stock on this one - a 1N5819 with axial leads would work electrically, but I'm not sure it will fit under there.

Steve's intent with that procedure was for you to listen with your TS-480 tuned to 9.999000 MHz USB for the 10 MHz calibration signal coming from TP1 of the ATS-3B and adjust The ATS-3B until you see that the audio tone from the TS-480 is 1000 Hz.

From: Steven Pituch
Topic: 2883 Message: 2888

Hi all,

Thanks all for the info on the ref osc calibration. It seems I had it 180 degrees wrong.

My next dilema is that my bee know seems to be stuck at about .1 WPM. It takes forever to announce the frequency. I had been able to change the cw speed and the annunciation speed before, but don't know what happened to put it in this state. When I go to change the cw speed it appears to take the commands but the speed never gets faster.

Any suggestions? I am going to do the calibration but at this point it will probably take a long time.

Thanks,
Steve, W2MY

2889. Missing parts - ATS3-B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-05 21:15:15 UTC
From: Stephen Wandling
Topic: 2889 Message: 2889

I've looked at the file section and searched through the messages and I don't find mention of anyone reporting missing parts. I guess I'm the lucky one. I am missing the six 0805 22k resistors (marked 223). I haven't inventoried everything, but I do have the rest of the SMT parts.

Am I correct in assuming that with Steve on the trail, there is no one manning the shop to supply missing parts? If so, that kind of blows my summer.

Maybe one of you won't be starting their kit for awhile and could 'loan' me those resistors?

I haven't, and probably won't, do a formal proofread of the manual, but I have noted errors. This surprises me as this is the third batch of these rigs. It would appear that previous builders knew that a 3.3 k resistor is not marked 392, but 332. But, for some, this could cause hours of confusion. As a project manager myself, I assure you that I would want to see feedback on issues like this. I don't see this as nitpicking, but providing a real service for the designer/kit supplier and a service to fellow hams.

That's nice but I expect he had some of the resistors
around in a collection. I think to ask someone to
break apart a kit is rather forward. The SMT parts are
really dirt cheap for the resistors especially.

wrote:

Stephen,

Sorry you were the unlucky one who had parts missing. This hasn't happened to many of us - the three kits Steve has sent me have been complete. Steve has been helpful and generous about correcting little things, including providing updated firmware for bug fixes, etc.

How Steve runs his business is his business, but we know Steve isn't Elecraft. He has provided several amazing kits to perhaps several hundred loyal followers. This group here is like a club - we have common interests and share information.

When we find a problem or have a question, we post it here. Usually someone helpful answers. Steve participates actively when he's not out on the trail.

I'd suggest looking at Mouser or Digikey for common components like the resistors you needed - if you need help choosing the right part, several of us here can probably assist. Yes, the markings on some of these parts can be challenging. This is one of the aspects of the elecronics industry that has not really changed. I still have boxes of old molded mica caps that have various patterns of colored dots on them - there were several codes used, and it's easier to measure them than to decode them!

Of course, the unmarked chip caps in our kits are even worse. If you mix these up, you'll need a capacitance meter to read them. I think it's amazing that the industry works this way, but since most high-volume assembly is automated, markings aren't needed.

Yes, there are a few errors in the "final" manual I have. An important updated ATS-3B schematic is posted in the "FILES" section here - Steve corrected various component designators, and you should copy and reference this drawing to avoid serious confusion. Perhaps your manual has been updated - but please check to see. There are still a few errors on this drawing - including that the driver IC is shown as 74HC02, even though it was upgraded to a 74AC02 in all the "B" rigs.

Building an ATS rig is a series of challenges. It isn't a beginner's kit, and some of us have had to do a bit more than just follow directions. I thought figuring out how to orient the various IC's was tricky, although I got them all OK. Steve's directions are

right. The alignment is subtle enough that you probably will do it at least twice, if you want your rig to perform as designed. If you want maximum RF performance on all bands, look at my notes on the filter modules. I spent more time on those than on building the rig.

The bottom line is that the ATS rigs were designed for field and trail use, and they're incredible performers. You can actually use these rigs out in the woods or at a campsite and make good QSO's, without carrying much weight. There are a few errors in the documentation, but the rigs are amazing. We're fortunate that Steve made this kind of technology available to us.

I just read your bio on QRZ - very interesting, and you're in a great place for serious QRP operating! Don't hesitate to post questions and share your experience. This is a positive group, with a range of experience and specialized knowledge about the ATS rigs.

Carey,

I have a bit of a quick trigger finger, and once again it has resulted in me implying more than I intended. Thank you for bringing some balance to the issue. (Speaking of balance, I note that each character in your call is a CW palindrome)

I meant no criticism of Steve, the rig or the kit. And in truth, I thrive on challenges. In hindsight, I think I wanted to challenge this group to give Steve all of the support they can, and that doesn't only mean just making positive comments on what they like about the rig/kit. I suspect that Elecraft didn't become who they are without quality control feedback, and that always includes what's wrong or could be better. Not that Steve wants to become an Elecraft.

Regarding the documentation, I discern between typo/spelling issues and errors. Chinese editors are said to leave a few typos in their publications because they know how superior it makes the reader feel when they find them. :-) But, an error could put a less experienced builder into a tailspin. Of course, that's what this group is all about; helping builders through the rough spots.

I'm here because the Old Goat, N0TU, and I almost had a QSO when he was on one of his treks on Mt. Herman (QSB ate us both). I figured if he could hear my 2.5 watts from Vancouver, BC, and I could hear him, with his 4 watts and EFHW hanging in a tree, then this had to be a pretty special rig. I can't wait until I can finish that QSO with him while I'm sitting on one of our local mountains with my Bee and one of Dennis Foster's "Micro" paddles.

From: Tim Davisson
Topic: 2901 Message: 2901

Am trying to find another ham in the
greater Akron-Canton-Cleveland, Ohio
area as an "elmer"/ham friend who can
offer advice in portable operation,
as I know nothing about these cool
little battery-powered rigs,antennas,
and what's involved otherwise.

Was inactive for 20 years...just got
back into the hobby a couple years
ago and the hams I now know are into
SSB or fixed operation.

Need some advice for portable QRP/CW.
(Any time I can do my ham hobby
away from home makes the XYL happy.
LOL, hi, hi).

Please reply to my e-mail address:
kd8gz@....

Thanks, guys.

72's,

Tim, KD8GZ
Norton, Ohio (near Akron)

Stephen,

Thanks for such an interesting answer! I think you're sure to enjoy
the ATS-3B and the experiences it leads to. I like to use the
word "magical".

I knew about my call, but I had to look up "palindrome".

N0TU sure has a unique station and companions...nice location down
there.

If you find yourself in a dilemma as you build your rig, just post
something here, and someone will reply with his version of the
situation. The most common problem seems to be parts that fly away!

2904. Nice case, OM. (7N4WBD's 3B in a Takachi MX2-8-13GS case)

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-07 22:13:47 UTC
From: kc7fys
Topic: 2904 Message: 2904

Without much fanfare 7N4WBD posted very nice photos of his bee in a
Takachi case. It appears to have required a little reworking of the
band modules, but allows space (apparently from the photos) for a
speaker and etc.
Very nice 3B, OM.

2905. NAQCC Sprint Tuesday night!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-07 23:30:33 UTC
From: Larry Makoski W2LJ
Topic: 2905 Message: 2905

This coming Tuesday evening will be the monthly NAQCC Sprint for April, 2008.

I will refer you to the proper URL:

http://www.arm-tek.net/~yoel//sprint200804.html

There you will find all the details as to time, frequencies, this month's Special Award, which will be awarded to the highest place scorer to make at least 5 or more contacts on EACH band (80, 40, 20 Meters).

This is a monthly event that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate; but you must use QRP power levels to compete for awards.

Come join us and have a real good time!

73 de Larry W2LJ
NAQCC #035

2906. CT 2 & 3 Help please

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-08 06:58:22 UTC
From: pswarman
Topic: 2906 Message: 2906

I have built the main board and so far only had one 'flying' component, I am now starting on the filter modules. For the 6 modules I have 8 green trimmers for CT2 & 3 and 4 brown trimmers. The manual mentions that all trimmers are brown with a colour coding on the side. The brown trimmers are higher value ones and I am assuming they are for 80 and 40 mtrs. I guess the rest will be suitable for any of the higher bands. This is a recently purchased model, has anyone else had the same issue and overcome it? I had planned on following the KX0R filter module tweaks.
Thanks for your time.
Paul, G0odp

Hi Matt,

I am also missing those parts as well as the two15 pf caps for the modules.

I just ordered a 190 part package from Diz, of Kits and Parts. This is a great deal and I will use the other components for mods later on. see: http://kitsandparts.com/

Date: 2008-04-08 23:45:41 UTC
From: w6zuluhotel
Topic: 2912 Message: 2912

Hello All: I am in the process of building one of the last batch of ATS3B's and have successfully reached the Check out and Calibration stage and the Reference Oscillator freq calibration, but that's where I "run aground"- namely the LO freq trim. I do not hear a "low tone" when switching to the CO step. I've checked the trouble shooting suggestions, no solder bridges that I can see, all voltages measure as they should be. I cannot hear the U2 4.9152 crystal oscillator.

What now? Suggestions?

TIA

Pete, W6ZH

Since you don't hear the LO I would suggest double
check all parts in that area. Especially the power
supply and the SA612 mixer (orientation, as well as
joints). Could be the audio chain especially since you
don't hear the tone, but I am assuming that you hear
the morse code feedback, right?, so that may not be
it.

One thing that can work is to use a toothpick (non
conductive) and press on the legs of the various IC's
involved while listening. This can sometimes pinpoint
a problem joint.

Do you have a scope? or RF probe?

Hi Pete,
I also have one of the last run ATS3bs. Check the variable capacitor on the main board CT1. I think its the bfo adjustment. Tweak it a bit and you might get the tone within audio range if its currently zero beat. Its actually the next alignment step on the next page. (Or maybe I'm way off here)

Matt,

These 2.2pf and 4.7pf caps are used for C6F on the various filter boards. The schematic in my "B" manual shows this cap as C9F, but that's one of those little errors some of us have noted. The PCB and the chart in the manual say C6F. This cap is used as the coupling cap in the double-tuned circuit for the receiver's front end. The caps in my kit are disc ceramic.

The caps are probably NPO (COG), and they're not critical. Since they're used for receiving, the voltage requirement is low, so almost any stable capacitors with the right capacitance should function OK.

NPO (COG) disc ceramic caps, MLC's with leads, MLC chips, and dipped mica caps should all be OK, if you can mount them easily. Tolerance hardly matters for these particular caps - 20% is close enough. Capacitors with such low values have a complex designation for tolerances, depending on the manufacturer and type - don't worry about it. If you don't have a 4.7 pf disc cap, but you have a 5 pf mica, go ahead and use that.

Suitable caps are available at various distributors, and they shouldn't cost much.

Good luck - if you need more help with the filter modules, please read my posted suggestions in the FILES section.

Done all that - and voltages on U2 are right on the money.

> I am assuming that you hear
> the morse code feedback, right?,

Yep, so the audio chain is not the prob.

> One thing that can work is to use a toothpick (non

Haven't tried that (yet) - will do.

> Do you have a scope? or RF probe?

Yep - have a scope, but haven't used it on the 3B yet. What
should I be looking for and where? Using a regulated variable lab-
type power source set at 10.5 VDC.

Pete,

1) Did you actually do all the steps prior to the "CO step", with a counter, etc., and get through all that OK?

2) Did your rig announce "CO"? You have to go through steps 1 through 7 and click the menu button to get the "CO" and that tone.

(For the rest of this note, please refer to the schematic in your manual)

U2 is your product detector and BFO. It's a double-balanced mixer with an oscillator on board.

You can verify if the BFO is working by using a scope on pins 6 and 7. Your probe on pin 6 may stop oscillation, but a good probe on pin 7 should reveal if crystal X5 is oscillating at 4.9152 Mhz. If you find no signal on your scope, try adjusting CT1 to see if the oscillator will run. This is your BFO frequency adjustment. If you still have no signal, try using a small capacitor, like 2 pf, on your probe to reduce the loading caused by the probe.

It's safer to probe the caps C11 and C12 than to probe the IC pins - be careful not so slip and short anything.

If the crystal is running, you should see some audio output - sine wave - on U2 pins 4 and 5. If the crystal isn't running, you should just see some weak noise. You can follow the audio through the chain to make sure it's working OK.

If none of this helps, try these general tips: 1) Isolate the problem by testing or probing relevant parts of the circuit - you want to narrow it down to one IC if possible 2) Use a very bright light and strong magnification to look for shorts or bridges. These can be hidden, and/or they can be tiny filaments, contaminants, or even some kind of defect in a board or component. Use a DMM to verify anything you think might be a short, if it's hidden, or the evidence points to it.

You haven't established that the entire audio chain is OK just because you hear the microcontroller sending code. The sidetone is injected part way down the chain. If you have audio coming out of U2 on pins 4 and 5, you'll need to find where it's not getting amplified

sown the chain of U3a, U5, U4, and U3b.

That's all I can think of without some more evidence.

One helpful hint:

On my schematic (and the revised "B" schematic posted here in the FILES) there is a reversal of the two audio lines between U2 and U3a. The board works fine, but some designators and the signal paths don't match the schematic I have. I believe the audio from U2 pin 4 actually ends up at U3a pin 3, and the audio from U2 pin 5 actually ends up at U3a pin 2. If you're probing that area you'll go nuts unless you know about this - it's just a drawing error - the board works fine. The two push-pull audio signals from U2 are 180 degrees out of phase, so there's no problem.

What about you Mike? We should be able to crack this one.

I want to thank each of you that responded to my plea for assistance with my ATS-3a. You may recall that when I completed the kit, I found that the receiver was quite insensitive, although this condition could often be momentarily relieved by tapping on the pc board, and the transmitter did not transmit. I decided, as a preliminary to taking my radio to a friend, who had the lab equipment to follow the suggestions that I had received, to systematically reheat every solder connection in the radio. This effort had the happy effect of reviving the transmitter! It nows puts out 2.5 watts with a 9v power supply. I did not identify the specific problem. However, despite this success, the receiver showed no improvement.

Keith, WB2NVY, kindly inspected and experimented with the radio. He determined that I was not adjusting the trimmer caps on the filter boards correctly. The receiver now performs excellently and I enjoy using it very much. So, I now know how to adjust trimmer caps! Thank you Mike, VE3EQP/W4 for pointing out this possibility. I also give a special thank you to Carey KX0R for describing the signal path through the radio and where to test it. That guidance was very helpful.

I look forward to beginning work on my Bee, however, to complete the toroids for the ATS-3a filter boards, I had to borrow the number 32 magnet wire from my Bee kit. I am having trouble locating a supplier for this wire. Is there some other term for such wire or do you know where I might find it?

Many thanks and 72/73, Dave K1YHR.

2926. Re: Help/suggestions needed

To Mike, Carey et all: Many thanks for the suggestions - here's a recap and present status of my 3B project using the manual as guideline:
A) Check & calibration:
1) supply voltage: 10.2 VDC, regulated
2) TP1 voltage 3.976
3) "8" heard in Morse & 8 on display on pwr-up
4) dot & dash ok on keying
5) pwr removed & L3 installed
B) Ref Osc. freq calibration
1) step 3 - "CF" heard & "C" on display on pwr up
2) freq counter connected to TP1 & osc set to 10.000,000 MHz.
3) clicked "Menu" & heard "CO"
4) a change in background noise, but no "low tone".
C) Steps taken:
1) tweaked CT1 - no change
2) using "sniffer" receiver tuned to 4.9152 MHz - no sign that U2 osc is working.
3) all voltages on U1, U2 and U4 as specified.
4) inspected U1, U2 & U4 closely under bright light (full-spectrum CFL - these are great) and max magnification of two-stage visor magnifier - no shorts, bridges, unsolder joints could be spotted.
4) I have not used my scope to try to see if U2 is oscillating.
D) - Why?

Here's the status report section: at 11:44 PDT yesterday my long awaited Elecraft transceiver K3 kit was delivered. Effective as of then, all work on the ATS-3B will be postponed until K3 #657 is up and running - then back to work on the 3B - stay tuned, please - and again, many thanks to Mike, Carey and the others who have offered assistance.
de Pete, W6ZH

From: pswarman
Topic: 2928 Message: 2928

It's built now and I'm testing with 40 mtr band. Two silly errors so far, I imagine the first one is easy to make so this is to warn other new builders. On first switch on the current drain was VERY high, I switched off quickly. Tracing back from the +ve supply I found the 3.5v side of U10 was at ground and this lead me to inspect more closely local joints for solder bridges and there it was. I'd tagged one of the connections of the 60Mhz ref. oscillator to the metal top..... I recall it was tricky to solder to the board and obviously I wasn't careful enough!

The second error was again a soldering problem... the logic didn't recognise it was a 40mtr plug in, it thought it was 15Mtrs. On checking the voltage to j1-3 it was at zero.... that didn't seem right and following it back I could see that one side of R44 hadn't been properly soldered to the board.

The rig is now receiving my sig genny..... pity the band is dead over here!

This is good fun. Pity I'm back at work next week.

2930. ATS3b: Power out on 40m

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-13 23:09:42 UTC
From: Steven Pituch
Topic: 2930 Message: 2930

Hi all,
I was getting about 2.3 Watts out at 9Volt at the plug with the standard 17 turns on LF2 (30 ga) squeezed really tight. I tried adding the 150 pf to C2F per KX0R, but power went down considerably (abt .6 W) even after playing with the spacing of turns for LF1 and 2. So I took off the 150 pf cap and rewound LF2 with 19 turns 30 ga. Now I get 2.5 Watts out at 9 V and the turns on LF2 are not completely squeezed tight. This was all done on a dummy load.

However, if I go to 12.00 Volts at the plug, I just realized the output impedance changes and the inductances of LF1 and LF2 are no longer optimum. I was only geting 3.4 Watts out at 12 Volts at the plug.

By readjusting the turn spacing of LF1 and LF2 at 12 Volts, I was able to get about 4.2 Watts out into a dummy load and about 4.0 Watts out into the antenna. However if I try to squeeze the turns more to get more power out I trip the current sensor.

Any suggestions or comments?

Thanks,
Steve, W2MY

--- In AT_Sprint@yahoogroups.com, "Steven Pituch" <list2@...> wrote:

Steve,

Sounds like you're having fun with your filter modules!
Experimenting is the key to getting the most from the rig.

Since my toroids were mostly wound with #26 wire, not #30, there will be some differences in optimum tuning and maybe in efficiency. #30 has a little bit more loss, but it offers a greater range of adjustment on the toroids, unless it breaks. I don't like #30, and that's why I went to #26, like what Steve supplied with the ATS-3A.

Toroids vary slightly from lot to lot. I count the turns by the number of wires passing through the core; this is the standard way to count them. I use a strong magnifier and count several times until I'm sure. Since the inductance varies considerably with adjustment, the exact number of turns is less important than the intuitive feel you get from adjusting the two coils back and forth while you watch the power output and the DC current being drawn.

I did raise my current trip point about 10% by adding a 5.6K resistor across R47. This was necessary in order to run the rig at 5W with 12V on the upper frequencies. I also tune ONLY into a bridge and use a resistor in series with the battery to limit the voltage and current while adjusting my tuner. This was discussed my several of us in earlier postings here.

With good adjustments, at 12.0V you shouldn't be above 0.8A DC in with 5W out on 15M, with an accurate 50 ohm load. That is my worst case. Current rises gradually with the frequency as you go from band to band. On 40M I get 5.2W out at 12.0V with only 0.65A. This is one amazing rig! I verified my WM-2 against a Norcal Dummy load with its diode detector. I also verified against another diode detector I have. The load must be accurate, and cables must be checked to make sure they're 50 ohms also.

My performance chart for all bands is posted in the FILES here - it's separate from the data on modifying the various modules.

I did all my adjustments with a 12.0V supply; but the efficiency and performance hold nicely with lower voltages on all bands. I get 2.9W or better on every band with a 9.0V supply. These voltages are measured at the connector on the board, but before the protection diode, so the final is actually seeing less voltage.

It's worth checking your current input, so you can see how much current trips the sensor. The sensor is tricky, since the rig's current goes up with supply voltage, adjustments to get more power out, and certain kinds of load mismatch. Even if you adjust your rig for 4W out at 12V, a minor mismatch might trip the sensor.

I think this rig really needs to have a good tuner, adjusted for a nearly perfect match, to behave properly; this is essential if you run on 12V. The rig doesn't fold back with SWR like commercial rigs, but it offers nice efficiency and low power consumption as a reward. Even a simple L network will make an ATS rig happy, provided it has a resistive bridge for tuning.

Good luck and lots of patience...

Hi Steve,

The difference between 2.3 and 2.5 W is +0.36 dB and from 4.0 to 4.2 W
it is +0.21 dB. Difficult to hear the difference in normal band
conditions.

The effective battery series resistance limits also the output power.
Thus the trick to use 10 ohm in series to avoid tripping while tuning
the antenna.

Googling gave me this

Hi,
Jaako,
Thanks for the info on the 10 Ohm resistor. I certainly would like to reduce the power when tuning up.

I was looking for guidelines for changing capacitances and inductances in the output section as far as increasing the power. It seems my 40 meter module is not too bad. But I just finished the 80 meter and 20 meter modules, and even though they receive well, I am getting only about 2W out at 12 Volts.

I realize that this kind of adjustment is sort of dangerous not having a spectrum analyzer to check for harmonics. KX0R's work is very informative, but again he tested his changes for harmonics.

I am having a ball with W1MT's scanning software version of the ATS3b firmware. I have expanded the scanning widths to cover the entire cw portion of the bands and just leave it on in my office/shack. I have it hooked up to a pair of amplified computer speakers that have a volume control.

Last week, I had a major problem with the radio going deaf unpredictably while tuning. I have been resoldering around Q1 and Q2, and resoldered the 4 corner support posts so they are more perpendicular to the board. It has finally gone away and am now thoroughly enjoying listening to the rig. I tried responding to a strong station during the GA contest yesterday but with him going too fast and the confusion of his previous call he responded to being W2MC in NJ, he didn't recognize my transmission. I'm going to realign the rig once more as I think I adjusted CT1 after doing the LO frequency trim adjustment and fear I may be sending off frequency (not sure).

Does anyone know of a variable volume control like the ones on the cheap headphones, that is sold separately without the headphones. My Koss Plugs are really nice, but don't have a volume control.

72,
Steve, W2MY in Texas

Price is $200 plus $40 if you want the nifty paddle.

Check the schematics. It's basically an ATS rig for 3
bands with built-in tuner. Same restrictions apply to
it as to the ATS rigs regarding supply voltage and
power out. Steve did use a different MPU than the ATS
rigs so the firmware is won't be hardware compatible.

Nice package for those who want it all in one package.

For all,

Carey's writeup is excellent, please check the files
section of the group for it.

I do something similiar but a little different: Here
it is:

First, I "adjust turns" on LF2. (CF3/LF2 is a tuned
circuit that is designed to suppress the 2nd harmonic
(~14.08MHz for the 40M band)). Check out <
http://www.arrl.org/tis/info/pdf/9902044.pdf > for
more information on this type of circuit.

Then "adjust turns" on LF1 to get the power I want.

Adjust turns means to add/subtract OR compress/expand.
I used standard formulas to determine what the number
of turns should be given the current CF3. In no case
did I change the # of turns more that 2 turns from the
designed values.

For the receiver filter parts you need to do similiar
calculations and may need to add some capacitance to
the tank circuits there. It's a double tuned front end
filter so check both. Again Carey's write up is great
for this area.

I don't give exact numbers as I believe that this
exercise if useful for anyone getting this far into
modding there ATS rig.

Always double check current draw. I have actually
adjusted LF1 to lower power out in some cases. :)

Went back and checked my notes and realized that I did
indeed change CF3 for my 3B. More inline with older
ATS designs. Here is what I did:

Band/CF3
80m /220pF
40m /100pF
30m /68pF
20m /47pF
17m /39pF
15m /33pF

With these values I did not have to alter the turns on
LF1 and LF2 much to achieve my goals.

Steve,

There is a photo of all six of my filter modules posted in the Photos section. If you go to the LARGE view, you can count the turns and how the toroids are wound and spread. This may explain some of our different results.

Otherwise we have to wonder about other kinds of errors. The power supply must be well-regulated - not a small battery - with short leads, etc. for any of these comparisons to be valid. The load must be 50 ohms, the cables 50 ohms, etc.

The "B" will easily put out over 6 watts on the lower frequencies, if you defeat the current limit, with a 12V supply. When adjusting it's easy to go right over 5 watts if you have everything going right. The efficiency can be better with 4.5W out.

Mike's approach is actually more sophisticated than my intuitive cut-and-try process of iterations.

I do know that you won't see the harmonics rise much unless you radically alter the output networks. Tuning for maximum efficiency with high output assures that the harmonics are controlled well enough.

I increased C4F on the 17M and 15M modules, because I put a scope on the final drains, and the voltage peaks were near the 60V limit for the devices. I got both better output and less peak drain voltage on 18 and 21 Mhz with more capacitance at the drains. My hunch is that if C4F is too low, the hard-driven mosfets are trying to switch almost like into an inductor, which tends to cause voltage spikes. I don't really understand this mod well, but it does work OK. I was lucky on this one.

Thanks Mike!

I just realized I said something confusing near the end if the last post - I mentioned C4F being increased for 18 and 21 Mhz, but that's a direct result of C1F being increased. C1F is the cap near the mosfet final drains. I found that if C1F is increased, then C4F must also be increased.

On Steve Weber's chart in the ATS-3B manual, C1F is 220 pf for 30 meters, 150 pf for 20M, and then it drops to only 22 pf for 17M and 15M. This didn't seem right to me, for such a small change in frequency, since most of the other values reduce gradually as frequency rises. So I arrived at values that worked better, I think, but I don't understand the network as well as Mike. I don't think I messed with C3F much, except once or twice, to see what happened. I actually think the rig is safer with some increase to C1F on 17 and 15 meters. I only have a 100 Mhz scope and a 10X probe, so hopefully one of you with a really fast scope can look at the drains and see what's actually happening. The probe ground return to the pcb must be very short.

It's late guys ...

I remember wondering the same thing about CF1 and
increased it proportionately for 17m and 15m like
Carey. I did not increase CF4 but probably should go
back and look at the drain results on a scope.

Don't go thinking I know what I am talking about, I
just know how to Google and find stuff that helps me
try to understand what Steve has done on these rigs.
He is the true wiz for this rig. :)

Thanks Mike and Carey for the advice on the filter mods. I now have a pretty large file of ATB3b printed material for reference. For now I put the rig in scan mode and listen to the receiver while working in my office. When I have a bit of time and am not rushed, I will examine very carefully each band module and slowly make adjustments until I am satisfied with each one. I think Carey said in his writeup that he spent more time adjusting the modules than time spent on building the rig. I have to believe that that is the way to go.

Thanks and 72,
Steve

Steve:

The simple answer is " highly probable." But, since it uses a different CPU than the ATS-3 the code will be a bit different.

The tricky part is similating PSK-31 on a rig with a Class C or E final (NOT a linear final). You don't just start with a low level signal at the RF level and then amplify it. It takes some "tricks" to get the Class E amplifier to "look like" it's a linear amplifier.

I'm sure the gurus who came up with PSK-31 simulation on the ATS-3a and b can figure out the subtle differences for the new CPU.

Hi Steven,

2 W is a little too low with 12 V.

Here is my copy-and-paste from SOTA reflector. Main thing is to see if there is dramatic difference between bands or if only small fine tuning would be needed on some bands. I have used the FT817ND almost always with 2.5 W, so I thought that around 4 W from ATS3B would be fine.

---start copy
For comparison my results for FT817ND with internal battery using Elecraft DL1 (about 10 % accuracy). CW signal and power set to 2.5/5.0 W nominal. Battery display shows 9.8 V in receive.

80 m 2.0 W/3.8 W
40 m 2.4 W/4.8 W
30 m 2.4 W/4.6 W
20 m 2.3 W/4.7 W
17 m 2.3 W/4.6 W
15 m 2.4 W/4.4 W
2 m 2.5 W/3.0 W

Actually I bought the DL1 to test ATS3B, so here are the results for that too. 8xAA alcaline battery (now 11.8 V) and 9 V battery were used. The total TX+RX current consumption is for the 9 V battery.

80 m 3.2 W/2.0 W/360 mA
40 m 3.1 W/2.0 W/430 mA
30 m 3.8 W/2.5 W/480 mA
20 m 3.9 W/2.5 W/530 mA
17 m 3.7 W/2.3 W/470 mA
15 m 3.5 W/2.2 W/470 mA

I think I will not bother to optimize the power more now.

Hi Gang,

I am in the process of wiring up my 3B in its enclosure. I have a touch keyer that will be included in the package. I do have one question for anyoine who has also integrated the touch keyer into their 3B. I plan to connect the output of the touch keyer module into the paddle inputs on the 3B. I have two key jacks one for my paddles and one for the touch pads, so I can have a choice. Will having the touch keyer connected cause any problem when running with paddles? Do I need to disconnect the touch keyer output from the 3B paddle inputs when using paddles?

Nice results Jaakko,

I also have an FT817ND here, and I found that the output is very close to 5 watts when set for maximum and run either from a 12V lead-acid battery or a regulated supply. I believe that the FT817ND employs power leveling. The output is almost the same on all the HF bands, and it doen't vary much as the supply voltage is dropped. I think your battery may be a little too low to make it roll back and limit at 5W. Some others claim that 10.5V, measured key-down, is optimum for the FT817ND at 5 watts.

I believe the DL1 can provide accurate measurments, based on how it works.

The ATS-3B is completely different from the FT817ND, in that the power output is approximately proportional to the square of the power supply voltage. It doesn't level - it leaps as the voltage is raised! This is why it's risky to run with more than 12.0 volts.

Since you didn't mention whether your transmit voltage is measured key down, I'm wondering what your actual voltage input is. 8 AA alkaline cells will run the ATS-3B very well, but I doubt that the voltage key-down is really quite 12.0V .

Power measurements and comparisons are best done with regulated power supplies. Not only is the voltage held constant through the keying cycle, but many supplies offer current limiting, which is helpful protection when doing experiments.

Your results indicate that you did a good job of adjusting your toroids. If you wanted to spend more time, I believe that you could get just as much power out on 80M and 40M as on any other band. The clue is that your current drain is so low at low frequencies - plenty of room to work with there. Unfortunately the toroids with more turns wound closely have much less of a range of adjustment, and on 80 meters, turns may have to be added or subtracted, or capacitors adjusted, in order to make significant changes. The only change I made from Steve's recommendations for the 80M transmit filter was to use #28 wire instead of #30 for LF1; I still had 23 turns. Of course your results may vary. It's pretty easy to experiment with capacitors C1, C2, and C4, just to see if the rig wants to put out a little more power. Try adding 47 pf or 100 pf to each, one at a

time, while watching the output and current draw. Just tack-solder the extra cap on so it doesn't slip.

The ATS rigs are slightly more efficient at lower frequencies, so I'm pretty sure you'll succeed at optimizing 40 and 80. Pushing 15 meters is more like rolling dice...

We have several inches of new snow here tonight, after 80 degrees yesterday afternoon. Typical Colorado spring weather.

You do not need to disconnect the touch paddles. At the output of touch paddles there are 2n7000 with open drain. You could safely connect a switch parallel to the FET.

Jonathon:

I felt that I would prefer to use paddles when at home and the touch pads in the field. I did not want to be lugging the Bencher around due to its weight.

When I get to building the touch pad base it will also include 3 tactile switches like those on the 3B for the Menu, Tune Up and Tune Down functions. I have a 4-conductor jack on the enclosure for this purpose for the 3 switch inputs and ground. This way I can check my frequency and tune from the touch pad base.

Instead of flat pads you can put them in a configuration like a conventional paddle. I have two examples at:

That's an ambitous touch key concept. I didn't like mine at first, but found it useful once pressed into service. It requires a bit of thumb moistening so's not to drop dits, and can't compare to good field paddles. But one less peripheral is quite nice.

I found this <http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=16540> interesting ham radio page over on QRPp list. I like the small field-deployable matching tuner in particular, but there are several novel QRP ideas on the page.

I have a request, too. I want to update my firmware--I gather that the current version is V3, correct? Once a guy's set up to do it, it's just a matter of moments in the execution, right? If so, I'd like to just bundle up my Bee and send it to somebody on the list here to do the update. Of course I'll include a small omiyage (souvenir) from JA1 with the return postage as well. Drop me a note if you would like to update my firmware. I'm simply not outfitted to do it myself.

And thirdly--this is a sort of simple question, but I wonder what y'all have been doing. I think it's fairly typical operation with the 3B to keep an 8-10 cell AA pack and 9V battery on hand--one for reduced power on tune-up, and the other for when the SWR is low. I was envisioning some kind of switch on my cheepy battery pack that would just switch me to lower power, instead of swapping out batteries. I already put a little toggle <http://farm3.static.flickr.com/2123/2424297720_0b48f37634_b.jpg> on, that has turned out to be very useful. What do you others do when you need fewer volts?

Jonathan,

Comments:

1) Great website - real ham radio with spirit; oriented toward true portable operation. No doubt the Z-Match tuner does many things well and allows operating on many bands with minimum hardware.

I built a Z-Match version of the BLT. Mine tunes 1.8 to 30 Mhz, with a single DPDT range switch. While it's an amazing tuner, the problem with the Z-Match is that it tends to have poor balance on the higher frequencies. This is due to capacitive coupling between the close toroid windings and the inherent assymmetry of the device. While I'm proud of my Z-Match's range, I did measurements with split balanced loads and proved that the balance is terrible on the higher frequencies. This means in practice that the Z-Match may deliver a seemingly nice match, but it's operating in common mode, so your lovely "balanced" antenna is operating as a T, with the feedline and horizontal wires fed single-phase against ground! This is particularly likely when the balanced line presents a high impedance in balanced mode - which is often true with these multiband systems. I like these kinds of systems and use them, but I mostly use one of my modified BLT's. These do much better on the balance tests. On the other hand, the Z-match is sweet if you plan to work with low feed impedances.

The double-tuned resonant circuit concept used in the Z-Match is many decades old, yet it has great potential for QRP tuners. There are probably configurations yet to be developed that may have better performance.

2) I know it sounds dumb, but the idea of using a resistor in series with the battery pack has merit. The ATS-3B really works fine with a 12V battery and a series resistor. I use 6.7 ohms with a switch on the 3-cell lithium pack. It would work just as well on an 8-cell alkaline pack. 10 alkalines is too much for the rig without a resistor or other regulator. Another great option is a series regulator, such as a low-dropout type. The resistor is compact and simple, and my rig likes it. Most QRP rigs won't work well with added resistance - this rig is different. Matching is easier and safer. This is a better idea than using fewer cells in the battery, since the current is limited more by the added resistance.

Another problem with changing the number of cells in that they don't discharge uniformly. This is a problem with all rechargeable cells,

and a disaster with lithium.

When someone else posted the resistor idea here, I thought it was dumb, and so I tried it and did various tests to see what it messed up on the ATS-3B transmitter! I couldn't find anything wrong with the keying, the spectrum, the break-in, or the digital stuff. The only problem is that if the resistor is too large, like more than about 10 ohms - more or less - the transmitter might not get enough voltage key-down, and then it could misbehave. It needs about 6 volts key-down. The voltage and current vary with the load, so this could be tricky. 6.7 ohms is real nice with a 12 volt battery.

Try it - you'll like it...cheap insurance, and safer matching when tuning unknowm antennas.

I use to also have two battery packs. One was a 9.6V, 8AA pack and the other was a 12V pack with 6 Cyclone batteries, both with the regular 12v coaxial pwr connector on them. All I had to do was unplug from one to the other but I feel your "pain". Now I have everthing in one box. Its not really a "trail" rig but it is very portable and works for my situation. I posted new pixs under my callsign in the photo section.

HI Jonathan,
First off I want to tell you that I really enjoyed your pictures on the Net. I studied the ATS3b pictures very closely before starting to build mine.

I am new at this but I needed to reflash my ROM after building my ATS3b. I made a cable in an hour using an old centronics parrallel printer cable and 7-220 Ohm resistors. It is very easy to do. After reflashing the ROM I eventually reflashed it again with W1MT's SW and now have scanning capability on my ATS3b. I even changed the scanning to go down to the bottom of the etxra band on all frequencies by just changing a few constants in the text file. It is very easy to do. I suggest you build the cable and do it yourself. It would save you lots of time, and as mods in the formware become available you can reflash the ROM in a few minutes.

Here are the emails about the cable.

Dave :

Checkout the photo section of this group in the VE3WMB ATS-3A folder.

It was easy enough to drill the AA-1 enclosure. The issue I had was that due to the extra thickness of the walls (as compared to an Altoids tin) and the difficulty getting the board close to the edge of the enclosure (there is extra aluminum in the corners to support the thumb screws that attach the lid so I had to trim the corners of the PCB for a better fit) I ended up having to drill the holes for the jacks bigger than I would have liked to.

In my case the jacks didn't end up protruding quite far enough through the enclosure to allow me to get a good connection with the power/phones/paddles so I had to make the jack holes a bit bigger to accomodate a bit of the body of the plug. I'm certainly no metal worker.The end result was ok but not perfect.

What I do like about this enclosure is being able to swivel the lid open (on the bottom) to change band modules by loosening one thumb screw.

2973. Re: Enclosure for ATS-3a

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-21 03:40:18 UTC
From: camqrp
Topic: 2963 Message: 2973

Dave -

I used the AA1 enclosure in lieu of an Altoids box for my ATS-3A and am very happy with it. In addition to being much more solid, it has room for all four band boards inside (during transit, that is!). Refer to the pictures in the Photo section under the title "N6GA's scope fotos". The scope fotos are long gone, but there are a couple shots showing how I dealt with the connector-end problem.

The board bumps up against the aluminum post in the corner which was left in to provide for a mounting hole for one of the thumb screws. The thumb screw doesn't travel very far into the box, so I took my Dremel thingie with a small grinding wheel and removed enough metal so that the board could be mounted flush against the end of the box. This way the outboard end of the connectors are almost flush with the outer edge of the box and the plugs make good contact when inserted.

Drilling this box is much easier than drilling an Altoids tin, and the finished result looks great. Especially if you use a stepped drill bit. When you finish drilling each hole to the proper size you can briefly touch it with the next sized step, leaving a clean-looking bevel on the edge of the hole.

Hope this helps.

Good Luck,

Cam Hartford N6GA

David :

No Issues with accessing the four control buttons, although somehow my holes ended up a little bit skewed (my fault) so I had to jiggle the board position a bit so that the buttons wouldn't bind.

The thumbscrews are on the bottom. As long as you use stick-on rubber feet that are thick enough there are no issues. I like the 3-M Bump-ONs, they come in various sizes.

I think that CAM's suggestion of grinding out the extra aluminum in the corners to make the board fit better is a very good one. Also as Cam suggested, it may actually be easier to drill the AA1 as material is much more rigid than the thin steel in an altoids tin.

I think that the AA1 makes for a slightly more rugged enclosure than an altoids tin.

Best of luck and be sure to post some pics when you are finished.

Cheers,

Michael VE3WMB

Cam,
Following up on your "during transit" comment regarding band boards,
why only during transit? Interaction between the active and stored
boards?

Thanks,
David

Dave -

The loose boards make for a pretty tight fit when the bottom's screwed on. I'd be afraid of a random short circuit, so I take them out. There might also be some interaction with and detuning of active circuits. In any case, I just feel safer with them out while I'm operating.

Cam

From: kc7fys
Topic: 2978 Message: 2978

This is a question for W1MT, but I'll ask it aloud on the forum FYI.
I built the cable, 6-220 ohm resistors on pins 2-7, pin 1 a bundle of 18-25 on the serial plug pins and the outer ground wire. Snapped photos through the process for posterity and reference.
PHOTOS HERE.
<http://www.flickr.com/photos/jonathancharles/sets/72157604664093736/>
I used 7 pin-sockets to fashion the plug, and just 'leaned' it into the 3b's board for contact. Started up IAR Workbench as per W1MT's link/instructions.
During the process the Bee buzzed, clicked, hissed, and beeped once or twice.
Everything was according to instructions until and through "Press CNTRL-D to start debug." After that, there was never a 'RUN' to press, nor was there specifically an 'EXIT DEBUG' dialog or clickable. So the process ended sort of inconclusively, with the IAR software just going back to the state it was in before the CNTRL-D compile process.
My Bee now works--sorta--which is even more puzzling, because I figured either the firmware would work, or I would get a dead bee. Instead I have a sort of Frankenbee. On powerup I get VM24 (pause) AT4TRT. That's got me scratching my head. (Perhaps I have contacted the other side.)
Initially, to verify the V1 firmware, Steve's original firmware--I did the DAH/MENU hold while powering on. I got a V1 followed by 8 annunciating the band module inserted at the time.
DFE works on 80, but there is no short beep indicating each number entered. UP/DOWN pressed at the same time gives me a 'dancing' LED' upper-left and lower-right flashing alternately with upper-right and lower-left. Battery voltage indication works. DFE annunciates the letter F instead of D.
I was running WIN98 on an old Thinkpad resurrected for the firmware flash.

So first I need to verify orientation of pins 1-7 on the 3B end of the plug. PIN1 is nearest the power jack. PIN7 under the letter R in PROGRAMMER stenciled on the board.

To what extent can I blow up my radio in this process. I fear I have. On the other hand, it's probably just a matter of tweaking my process, then I'm on track.
Jonathan

HI Jonathan,
Nice photos. It looks like you got the ground (pin 1) correct. Its the pin farthest from the band module and the inset in the photo shows it correctly.

Originally I got an error that the processor was incorrect. I looked at the chip (I have one of the 6 latest ones) and it says M430F1232, I put that in and then it worked perfectly. Apparently different CPUs were used at different times.

The run and exit debug are buttons that appear when
you enter debug mode. Mouse over them to figure out
which are which.

> On powerup I get VM24
> (pause) AT4TRT.

Version Mike 2 Band module 4

Seems the menu button is down. It should only announce
version when the menu button is down during boot or
reset.

> I got a V1

Programming seems to be a binary event. Either works
or doesn't. As Steve P mentioned make sure you chose
the MPS430F1232 in the options menu (I think you did
or it would not have flashed the firmware.)

When you power up without touch any buttons do you
hear the version announcement?

Mike has been very good explaining his firmware to me. I really like the scanning option.

As a side note I made 7 contacts during the Run for the Bacon on Sunday night here, so my ATS3b is working great. I have debugged and potted the 80 meter and 40 meter modules. I need a lot more time to debug the other modules. I have made some significant changes and will report on them later. It seems I have quite a few few missing parts for the modules but I think I can substitute for them with what I have in stock.

I can't believe the performance of this rig. It puts most analog single band QRP rigs to shame.

Hi Jonathan and All,'
I d cided to use one drop of 5 minute epoxy at each toriod hole. I let it seep down to where it contacts the board. It attaches the toriod to the board and the windings to the toriod. I read that someone else said epoxy was OK so I just did it. If I need to readjust the windings later on I will have to take the toriod off of the board remove the glue and wire and rewind them. But I have done that before so I think this is the easy eay to secure the toriods.

I don't think hot glue works as well and I have had just as much trouble removing the hot glue from the toriods so I went with epoxy.

I also have several npo ceramic caps that overhang the module boards a bit so I dabbed some epoxy on those too. Very secure. Pictures later. The caps I ordered from Diz at Kits & Parts have really come in handy.

Regards,
Steve

2990. QRP To The Field - this Saturday (April 26)

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-23 22:49:35 UTC
From: scott mcmullen
Topic: 2990 Message: 2990

This Saturday (April 26) is the annual 'QRP To The Field' contest.

Should be a fun event to bring a QRP rig and antenna to and make
some contacts in the great outdoors.

The theme this year is to operate from the grounds of a museum,
though there are other station categories also if a museum is
not convenient.

The rules in full are at:

http://www.zianet.com/qrp/2008/qttfruls.html

73
Scott
W5ESE

QRP To The Field 2008 -- Days Of Yore

Date: Saturday, April 26, 2008

Time: 1500Z Apr. 26 to 0300Z Apr. 27

Bands: 40-20-15-10 meters, in the vicinity of the QRP calling
frequencies, please be courteous to others

Mode: CW only

Power out (QRP only): 5 watts or less

Categories: Single Op Museum station
Multi Op Museum station
Single Op Field Station
Multi Op Field Station
Home Station

Exchange: RST + SPC
Example: 559 NM

Scoring: QSO pts - 1 pt for each QSO per band
SPCs pts - count once per band

Bonus points: Use SPCs received to fill in the blanks with the state
abbreviation whose FIRST letter matches the individual
letters in the words "Olden Days" without duplicating
states. Remember to use the summary sheet, or you will
miss out on the extra points.

Each letter filled in is worth 100 pts (up to 900 max)
Example: A=AZ, D=DE, S=SD, L=LA, etc.

Note: Wyoming (WY)= Y; North Dakota (ND) and South
Dakota (SD) can also count as N or D, S or
D, but not both N and D, or S and D; E is a given,
be sure to count it in your bonus score

Location Multiplier: Museum station = x5
Field station = x3
Home Station = x1

Final Score: Total pts x Total SPCs x Location + Bonus Points = Final
Score

2991. SSB from the 3B receiver.

From: kc0vkn
Topic: 2992 Message: 2992

After having the kit kicking around for many months, the 3B's got me off my rear to get it done.

I'll need a travel rig this summer, and, I wanted to do some operating from Dayton.

After finishing the rig and the 40M filter last weekend, I finished the 80, 20, 30M filters today.

Now, when the next batch of 3B's are announce, I can justify getting one :).

So far I enjoy the rig. I haven't made a QSO with it yet; I've done lots of listening.

So, see you on the bands!

KC0VKN, Joe

2993. ATS3b Power Out

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-27 17:43:45 UTC
From: Steven Pituch
Topic: 2993 Message: 2993

Hi all,
I have been spending the last couple of weeks trying to optimize the band modules. However, I may have created a mess and might have to start over from scratch.

For my test setup I was using my existing tuner and a switch that was also connected to the same power supply and another transceiver. I was transmitting into a dummy load but apparently was not getting correct current readings. I figured there was a problem when the negative power lead was disconnected and the ATS3b still operated. I think the ground on the coax was completing my power circuit. Anyway, I disconnected everything and started from scratch attaching the ATS3b antenna jack to the OHR WM-1 and that directly to the dummy load. Now I am getting believable current readings. However, they appear to be higher than desired.

To top it off I was using the WM-1 on peak power. (I added a cap and a switch to do this), and it was reading a little low. I now use the tune mode on the ATS3b and have the WM-1 on instantaneous and the power reading on the WM-1 is now slightly higher.

I think I am reading current draw correctly now. I get about

These are my readings so far for 12.00 V:

80 meters: 5.1 W, .88 Amps
40 meters 5.2 W, .93 Amps
30 meters 5.2 W, 1.01 Amps
17 meters 4.1 W, .99 Amps

Previously the current limiter was kicking off all the time so I did KX0R's mod by adding the 5.6K resistor in parallel to the 680 Ohm resister at R47, but it was still tripping at about .7 Amps as I recall. So I removed both resistors and installed a 470 Ohm resistor for R47. The 17 meter module was adjusted after I had access to the current readings. It still seems high.

The mods that I made to the modules so far are as follows:

80 meters:
C7F was added, 22 pf to center CT2
LF1 was 23 turns, now 21 turns
LF2 was 26 turns, now 28 turns

40 meters:
C2F was 680 pf, now 860 pf
LF1 was 15 turns, now 14 turns
LF2 was 17 turns, now 18 turns

30 meters:
C2F was 560 pf, now 607 pf
LF1 was 12 turns, now 11 turns

LF2 was 14 turns, now 15 turns

17 meters: (still experimenting - preliminary settings)
no changes yet.

I still have a funny feeling that I have a problem before the final amp, perhaps not enough drive from the previous stage?

I definitely don't have the knack. My current readings are much higher than KX0R's.

Steve, W2MY

--- In AT_Sprint@yahoogroups.com, "Steven Pituch" <list2@...> wrote:

Steve,

Your power readings look great, but the current readings do seem high. Please forgive me for asking blunt questions, but I want to help here:

1) Can you verify your current measuring device? One idea is to insert an accurate resistor, like 0.10 ohms, 1%, in series with the original current meter and measure the voltage across the shunt. Use an accurate DVM. This is a second ammeter. You should have agreement if your first ammeter is accurate, and the resistor and DVM are accurate. Use whatever "standards" you have available to confirm the accuracy of each part of your measuring circuit. Many ammeters are off - on a DVM the amps range may have a large error. Sometimes the internal shunt resistor is damaged through "accidents", and we don't always notice.

2) Measure the current in the positive supply lead, with no other stuff hanging on, paralleled, or involved. As you realized, the ground return to your power supply should not go through the coax. The RF output should go only through the WM-1 and to the dummy load. These devices should not have grounds or returns, just coax leads, for these tests.

3) Measure your supply voltage near the ATS-3B power supply connector, before the internal schottky protection diode, to get agreement with my setup. All my measurements are taken key-down. The voltage measured with the key open is not very relevant; there will be a drop when the key is down. Use a regulated power supply with an adjustable control so that variations under load are minimal.

4) Have you checked your WM-1 for accuracy? The method in the manual is OK, but it has limited accuracy. Measuring RF watts accurately isn't easy, unless you have access to a calibrated lab power meter - and even with some of those you need power attentuators, which are a source of error. The easiest way I know to do a pretty good check on the WM-1 is to use a schottky diode detector to measure the RF peak voltage into an accurate 50 ohm load, and compare this with the WM-1. When I use the detector, I take the reading from the DVM, which is close to the RF peak voltage, and add 0.25 volts to that to correct for the drop in the schottky detector diode. This is an approximation, but it helps with the accuracy at 5W. The corrected peak voltage is used to get RMS volts - multiply by 0.707 - and then we compute power as Vrms squared divided by 50

ohms. The Norcal load has a chart, which agrees well with this. I would suggest avoiding any kind of peak power readings - what you want here is CW, and you want to watch for droop as the final mosfets heat up. For any measurements to be useful, it's essential that the load is really 50 ohms, and the voltmeter must be accurate. I used a Norcal dummy load with its on-board schottky detector to confirm and calibrate my WM-1. I checked these two against a third device, another schottky detector and load. All the loads should read 50 ohms on an accurate DVM (which you check against some 49.9 ohm precision resistors just to be sure). All the cables used in the measurements must be short and checked for flatness at the frequency you're running. I use an MFJ-259B for this, but there are other ways.

5) I found that my scope was not accurate enough for these measurements. If you have an accurately calibrated scope, you may do OK with that, measuring right at the input to your load.

6) It just happens that my FT-817ND measures very near 5.0W on all the HF bands, running on 12V. While this is not a calibrated source, it gives some confidence.

7) If you have access to a calibrated lab-grade wattmeter, use that as a check on everything else.

8) When all of your measurements agree within several percent at several different frequencies, you can have some confidence that you're getting control of your errors. All measurement devices have errors.

9) Even at the one-percent level, several instruments may add up the wrong way and push the total error to several percent. This is why we check with other instruments that are independent.

10) Of course, the only correct way to make accurate, reliable measurements is to use accurately calibrated devices that are all traceable back to lab standards. For most of us this isn't practical, so instead we use the best stuff we can get, and check it against other good stuff. Hopefully most of it stays pretty close, and we catch something that falls out of spec before it misleads us badly. We also try to correct known errors.

I think you MIGHT be seeing a sum of errors situation. If your WM-1 reads low, and your ammeter reads high, and your load is several percent off with a slightly weird cable, etc., you could see numbers like what you have.

In addition there could be several percent errors in my numbers in the other direction!

If the ATS-3B driver is weak, I think the output AND the current will fall. You can check the gates of the finals with a good scope and probe, and you should see a fairly rectangular wave. The wave is

best at the lower frequencies.

I'm wondering if you squeezed and spread your toroid coils to optimize your power and current while doing your measurements. You didn't mention it. Since you made small changes - just one or two turns - I'm wondering why you did that, since you can get the inductance to change more than just adding or subtracting a turn or two by the closeness or openness of the windings.

I do know that there are many good combinations possible from any one filter module. What I mean is that you could alter LF1, LF2, and C2F, and come up with several good results that give good power and efficiency. You might go nuts trying to find the ideal values.

Since Mike W1MT got similar results to mine, I think the radios and components aren't very different.

It would be nice if some others posted their results here, if they've had the patience to get into these adjustments seriously.

I don't know about yours, but my WM-1 doesn't track across its scale very well. I calibrated mine on the lower ranges as best I could, but I can see errors. I never could achieve good agreement from range to range and across the scales. It's still a very useful device, but not a lab standard. It does seem to hold adjustment well.

Good luck, and thanks for posting your results and questions. This is real ham radio, and it's a test of patience for sure.

> Hi all,
> I have been spending the last couple of weeks trying to optimize the band modules. However, I may have created a mess and might have to start over from scratch.
>
> For my test setup I was using my existing tuner and a switch that was also connected to the same power supply and another transceiver. I was transmitting into a dummy load but apparently was not getting correct current readings. I figured there was a problem when the negative power lead was disconnected and the ATS3b still operated. I think the ground on the coax was completing my power circuit. Anyway, I disconnected everything and started from scratch attaching the ATS3b antenna jack to the OHR WM-1 and that directly to the dummy load. Now I am getting believable current readings. However, they appear to be higher than desired.
>
> To top it off I was using the WM-1 on peak power. (I added a cap and a switch to do this), and it was reading a little low. I now use

the tune mode on the ATS3b and have the WM-1 on instantaneous and the power reading on the WM-1 is now slightly higher.

2995. Re: ATS3b Power Out

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-04-29 13:42:18 UTC
From: Steven Pituch
Topic: 2993 Message: 2995

Hi Carey and All,
Thanks Carey for your thoughtful and detailed reply. It is exactly the kind of wisdom I was looking for.

I think I purchased my multimeter after speaking with Wayne Burdick after building my Sierra. I did purchase it to check RF power. That would put it at over 10-12 years old. It is a Radio Shack 22-168A. It always seemed to be a nice tool. I hardly ever check current with it, mostly just resistance and voltage. I don't have anything else to compare it to. I think its time to consider buying another one.

The dummy load in my MFJ 949 E is reading 56.7 Ohms. There's 13 percent right there! I can't back figure the math, but hoping this means that my Watt meter is reading low. I suppose you recommend the Norcal Dummy load. I was reading about the Accuprobe which is OP amp compensated, but the Norcal calibration chart seems adequate enough. I had had built two other more accurate dummy loads years ago but discarded them after a few moves because of the leaking mineral oil.

I would appreciate any advice on purchasing a decent multi meter. There are so many out there now. Should I stay away from auto ranging? It there one out there better than others under $100. Etc.

The way I adjusted the output filters:
I studied all the available documentation. I tried adjusting C3F as Mike had suggested and C4F as you had in a few cases but found that only changing C2F had a positive impact on the output power. I would first peak the module with the stock LF1 and LF2 number of turns by compressing or expanding the turn spacing. If I got to a fully compressed or expanded toroid, if I thought that adding or subtracting a turn would help I would try that. Otherwise I would add about 20 uF to C2F and try again. Often after doing this I would have to add or subtract turns to get to an optimal range. It seems that most of the time expanding turns on LF1 initiated a current trip, while expanding turns on LF2 would increase the power out incrementally. I did this for hours at a time until I got the apparent 5 W out. Of course some of the copper traces are gone at the toroids since I replaced them about a dozen times for each module.

As I said earlier I was tripping the current limiter at about 4 W I think. I got 5 W out on 40 m after doing your mod of R47, but it was on the hairy edge when I hooked it up to an antenna. That's when I replaced R47 with a 470 Ohm resistor. It wouldnake sense that maybe I am actuaally putting out 5.5 W or more and thus the high current.

I have the feeling that my power readings are one-half to one Watt too low.

73 and thanks again,
Steve, W2MY

2996. VM2 Firmware Features

Yahoo group: AT_Sprint (2002 — 2008)

From: kc7fys
Topic: 2996 Message: 2996

Well, the firmware upgrade to the W1MT Version "M2," despite all my fussing about reducing my 3B to "Frankenbee"--was a success. Just to make sure I didn't end up casting aspersions on Michael's firmware, here's what I experienced:

I was not fully prepared for some of the differences in feel. The differences are good, but take a tiny bit of getting used to.

--DIT annunciation on scan up/down every 1Khz
--Steve's speed up/down had a slowing/speeding up dit that went with adjustment which is not present in VM2
--Obviously the 'scan' function is great to listen to while cleaning up camp, etc.
--A variety of new patterns on the LED
--DFE uses no confirmation beep after each digit is input, but thankfully, is present in the 80M mode

I really like this firmware, and Michael is patient with newbies who want to tweak the code for their own needs.

I am not a digital mode user, but would like to think I could use the rig for that. I would need to zap Steve's firmware in for that purpose.

It's fun working with the firmware, says this newbie.

Steve,

You've really done a lot of serious work on your rig! Sounds like
your method of optimizing is good, but you may have succeeded in
getting to much power out of the rig! I think an ampere going in,
after "matching", is too much.

Your dummy load error is significant. You may be able to correct it
close to 50 ohms with a parallel resistor. It would help a lot of
you could check it with an antenna analyzer at RF.

You RS meter may be fine. They key is to check it against
a "standard", such as a multimeter that has been recently calibrated
against real standards. If you can measure volts accurately, and you
can get 1% resistors, then you can check and measure current; you
also can find any error in your meter's current scale and correct it
somewhat.

The WM-1 may not read accurately when connected to a non-50-ohm load.
The cables will transform the non-50-ohm impedances into different
complex values also.

One warning is that once you get everything at 50 ohms, your ATS-3B
may deliver even more power than now, so the current may go too high
and the power out may be excessive. I hope not, but this might
happen. You may have to go through one more round of tweaking, since
the rig really needs to be set up for reasonable currents, good
efficiency, and a 5.0 watt maximum into 50 ohms.

I think you have more patience than I do.

At least we're pretty sure you're a victim of measurement errors
adding together.

This is partly why corporations with many pieces of test equipment
spend huge sums doing scheduled calibrations and getting
certificates, even when the equipment seems to be just fine.

Hang in there!

From: Bill
Topic: 2998 Message: 2998

I got my B working this week. It's not finished yet, but its good enough to put on the air. I only have the 40 and 20 meter band modules finished. I am really enjoying using the radio and find the receive is much better than I expected. I had the pleasure of building a KX1 recently and the rx is just as good on my B. I am very pleased.

I want to redo my altoids tin again. What is the secret to getting the board close enough to the edge, so the jacks protrude? I have been using a demel bit number 125 and it makes short work of cutting a tin. I ruined the first tin, I used the hole size in the manual for the 4 screw holes which was 3/16ths. 3/16ths is larger than the screw heads.

This was my fist time using the Cash Olsen method of soldering. When I first started the build, I didn't think my eyes would let me do it. It was rough, but I did it. The hot air method of soldering worked so well, my board looks like it was flowed by Kenwood. Made me wonder how many ATS kits get bought but never built.

I do have one minor problem. My kit was the last one Steve mailed before he left. The 7th from the 3rd batch. Anyway, I am missing 2 - 2.2pF ceramic disc capacitors. Is there a kind soul on the list that could mail me a couple to my QRZ address, please. I'll gladly pay by return mail.

Just wanted to add that the proud recpient of that KX-1 is me. You see Bill is my Elmer who is a highly skilled builder so when I bought the KX-1 kit he was happy to build it for me.

Bill, we need to try for a qso on these two builds.

Hi Bill,
Also check to see if you have the two 15 pF caps as I had them also missing.
Also I had two extra T37-2s and two fewer T30-2s. The T37-2s will work in a
pinch but are a little big.

Thanks Steve, I was missing 3 - 2.2pF and 1 - 47pF ceramic disc capacitors. I got a few extra parts too. I was able to scrounge one 2.2pF from an old vcr, but still need 2 more. I found the 47pF locally, but no joy with the 2.2's. So, I really just need 2 - 2.2pF's.

Thanks for the comment on my keys. I never intended on collecting keys, but now find myself with a serious problem. I see a key that I like and I'm like a junkie on crack. I got to have it, if I can't buy it, I make it. I uploaded a more recent key lineup photo at the bottom of the page for you.

Any comments on the secret to getting the PCB close enough to the edge that the jacks protrude from the altoids tin? I thought about taking the jacks off the board and then marking the 4 screw holes from inside with the board as far over as it will go?

Before I close this, thank you Rich KB3OMJ for the kind words about my building skills. The truth is, lots of the guys on this list are WAY out of my league. My eyes are not what they once were and I don't have my test equipment any more. But thank you for the kind words.

HI Bill,
The two mounting screw holes closest the three jacks need to be "almost" against the case. The board needs to be filed down "almost" to the two metal standoffs. With this, the three jacks "almost" protrude.

I hope this "almost" helps you. ;)

Bill,

I just noticed your request and have before me an envelope with
10 2.2pF NPO caps that look identical to the ones in my kit. I
would be happy to send 2 of them to you. If your QRZ address I will
send them out to that. I sure appreciated it when Bill Noyce sent
some caps that were missing from my kit. Thanks for the
opportunity to return the favour.

72,
Stephen

3015. PFR-3 BS170 RF Mosfets

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-03 23:55:17 UTC
From: radio_kx0r
Topic: 3015 Message: 3015

All,

I've been looking over Steve Weber's circuit for the new PFR-3 transceiver on Doug Hendricks' website:

http://www.qrpkits.com/pfr3.html

See the preliminary manual - download the pdf.

Much of the rig is very similar to the ATS-3A and B, with the BLT and 4-digit display added. It looks like a real nice combination in one box. Various pros and cons - very tempting!

One interesting point is that the three 2N7000 RF final mosfets used in the ATS rigs have been replaced by BS170 mosfets. Both of these devices are TO-92, and the specs in the data sheets are very similar. It looks to me like the BS170 can handle more current, and it has a better thermal resistance spec than the 2N7000.

The BS170 may have larger capacitances than the 2N7000 - a possible drawback.

Some of the differences may be related to how the specs are measured - I can't be sure if the comparison is "apples to oranges".

How long until one of us pulls the 2N7000's out of our ATS-3A or B, replaces them with three BS170's, and reports whether they work better or worse?

No doubt Steve Weber and Doug Hendicks changed the output mosfets for good reasons. I doubt that it was cost, since the BS170's are a few pennies more - and both mosfets are dirt cheap. My hunch is that the BS170's are less fragile, but so far I have only a hunch based on some slight differences between two similar data sheets.

Has anyone in our group worked with the BS170? If this is an upgrade path for the ATS rigs, we need to look at this seriously!

Since I've got both my rigs all tuned up for the 2N7000's at 12V and 5W, and they run real nicely, I can't get wildly excited about messing with those filter modules again !!! (If it ain't broke don't fix it, etc.)

The other mysterious question is why did Steve upgrade the driver IC from the 74HC02 used in the ATS-3A to the 74AC02 used in the ATS-3B - that was done to get better drive and efficiency on the higher frequency bands on the "B" - and now the PFR-3 goes back to the 74HC02 - makes some sense since the PFR-3 doesn't cover 18 and 21

Mhz. This suggests that the BS170's are easy to drive.

Has anyone here tried replacing the 74HC02 in the ATS-3A with a 74AC02? It might make 20M a little hotter on the "A" rig. I'm tempted, but wonder if one of you has gone first?

How about those BS170's ??

It wouldn't be hard to replace the 2N7000's - amazing that I haven't blown one of them yet!

3016. Power Measurement

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-04 00:09:23 UTC
From: Steven Pituch
Topic: 3005 Message: 3016

Hi All,
To properly adjust my output filters on my ATS3b band modules, I've made a pretty accurate dummy load.

I am planning on using the diode detector shown in Figure 7, on page 146, of "Solid State Design" to measure RF Voltage at the antenna jack. Seems to be a fairly accurate way to measure output power at 5 Watts. Any comments?

Note the output power is computed by V*V/(2*R).

Steve, W2MY

3017. 2N7000 Mounting

I guess I was trying to SPRINT across the finish line. Too often I forget that its the voyage and not the destination that is important. Or maybe subconsciously I thought it wasn't right for those three FETs to be bowing down like that. Anyway, mine don't.

From looking at photos on the site I gather that using the PC board as a heatsink was something that came with the B? Regardless, how much trouble am I in? I have them jammed down pretty close to the board, but if I de-solder the middle connections I might be able to bend them down enough, MAYBE. Then I would need jumpers to connect the middle pins to the board. But, I suspect that the two outer leads are too short to allow the case to be tight to the board.

Or, I could cut a piece of 1/8" aluminum and glue it to the board and snug to the FETs, but that might also inadvertently glue the FETs onto the board. Or, bend some pop can aluminum to snap onto the 3 FETs and also rest on the board, but that might come loose.

Or do nothing, and hope for the best.

Am I the first to create this situation? Any ideas as to how to proceed, and end up with a reliable rig?

Thanks,

72,
Stephen

If you aren't going to do much with the digital modes
I would leave it.

If you are going to do much with the digital modes I
would still leave them until they blow then replace
them.

Either way I think it's better to do a clean replace
rather than try to bend what's there already since the
leads are so short.

Who knows you may never need to replace them.

Hi Stephen,
I have wondered about this also. I got my 7000s pretty close to the board but are probably not touching. It would seem best if they were cemented down to the board with some type of thermally conducting adhesive. Otherwise, the only way the heat would get to the ground plane would be via thermal radiation, not conduction. In which case the 7000s might be better off mounted straight up to have better air circulation. But they would probably interfere with the band module. However, I am very rusty on my thermodynamics.

If I were you, I would probably leave yours alone. I plan on stocking up on some 2N7000s as they seem to be pretty cheap.

Steve, W2MY

Hi Steve and all the exceptional knowing folks,
I had the occasion to find a new set of 2N7000, so while cruising the catalog, found a page of various specs for the 2N7000, the question, other than the price, the main difference appeared to be the robustness of the different models, does this difference allow for more tolerance to high swr, or more effeceincy or both or none, in our beloved AT?
Thanks,--... ...--Dale - WC7S in Wy

I wouldn't consider thermal conduction through the case to be
a significant path of cooling for these parts. Even if you
were to mount them flat to the board with thermal goop it still
won't change the thermal resistance from the die through the
package, which is pretty high. The primary path of heat from
the die to ambient is through the device's leads. In that
case having the shortest leads possible to the PCB, and using
a suitable surface area of copper on the PCB from there is
the most effective passive cooling you'll get. If you run
a duty cycle that will push the FET's past the limit regulary
as in the aforementioned PSK service, then you might revisit
a more thermally conductive solution than the PCB. I don't
think Steve ever anticipated this rig to be anything more
than a CW rig with CW duty cycles.

Thanks for all of the responses from everyone. I'm going to leave
them as they are for now and replace them if they fail.

[I was visiting Diz and Dan's sites last night and will be putting in
an order of some of their packages, and one has a bunch of 2N7000s.
Just getting back into this hobby after 50 years, so I don't have a
junk box yet. But, I do have a box of consumer electronics to strip
parts from and plan to use the heat gun for that.]

I will check today, but the only unresolved issue is whether there is
a conflict with the filter board. I don't think there is.

I like the idea that the rig handles digital modes, but my immediate
usage will be CW. Plus, I don't plan to be QRO like some of you
(5 watts!! :-)) and will be content to run a cool 4 watts or so.

My goal is to have the Bee on the air today!

Stephen,

The ATS-3A and B manuals are very clear on how to mount the three
2N7000 RF power mosfets, but there is no explanation other than that
the board acts as a heatsink.

I mounted mine as flat as I could get them, and I got them to touch
the board by pre-bending the leads prior to soldering. However, I
agree that the leads provide a path for most of the heat to get out.

In the new PFR-3 Steve Weber sorta-clone-of-ATS-rig on Doug Henricks'
site, the three BS170 final mosfets are mounted straight up! Another
part of the BS170 vs 2N7000 mystery.

How come none of you guys said anything about the BS170's mentioned
in my previous post - I'm puzzled that no one responded to this so
far - too bad Steve Weber's not around. I plan to ask him about this
change, just in case the BS170's are really an upgrade with a little
more safety factor.

If you do blow out a final, it may be the zener diode that goes
first. It might short and protect the mosfets. My scope
measurements suggested that on the higher frequency bands, the peak
drain voltage is pretty high - the diode may actually be clipping a
little if the load's not quite heavy enough.

Since no one's complaining here, it must not be much of a problem.

Stephen, if your rig runs well with the mosfets stright up, please
come back here and let us know after you've put some serious hours on
them.

I know this - that after a half-hour ragchew on 20M, at 5W out, my
altoids box case is noticeably warmer than before the QSO...

When Steve W and I discussed the DDS losing-lock problem last year,
we were heating our rigs up with heat guns until things were toasty.
That was at 5W, 12V, and key down for a while...the mosfets never
blew. The driver never blew.

This is one amazing rig!

Someone's going to get 10W out of one before long. Try 6 BS170' and
a larger driver? How about a single IRF510?

3024. 2N7000 vs BS170

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-05 02:02:47 UTC
From: WA0ITP
Topic: 3024 Message: 3024

I looked at 2N7000 vs BS170 data sheets a coupla weeks ago. I think the main differece is that the 170's are rated at 830mw, the 7000's are 400 mw. So I'd guess the main reason for the switch is that Steve wanted a more robust final.

Incidentally, Doug had the prototype PFR-3 at OzarkCon ... vy impressive..

I love this radio stuff !

I doubt running 6 in parallel would work, the devices are never going to be perfectly matched when in different packages, using 2-3 you can usually get ok results but going up higher is not going to get much of an improvement because one device will act as a master and be producing the majority of the power, this device would eventually catastrophically fail. IRF510 might work, but its output capacitance is going to be substantially higher than a 2n700. I'm holding my breath for some of the 8pin soic GaN on Si fets coming out at MTT. very low capacitance, for driving class E they might work great.

You're right Terry, the BS170 has twice the power rating of the 2n7000. The other -major- difference is that the pinout is -reversed-. This is something to take into cosideration if you are thinking of plopping them into your ATS rig.

To me, there is no real mystery why the change. remember that the new PFR-3 is a conglomeration of past efforts. Dan Tayloe's NC2030 used BS170 in the output stage, and these proved to be robust devices (although I -did manage to blow a few. (he he). The resistive SWR bridge in the new radio is also dan's design. Anyway, since Doug has the benefit of two great designers (Steve and Dan), we all reap the rewards of collaboration.

I dont have SSD, but wonder about the V*V/2R calculation based on voltage at the antenna jack. No doubt the design of the probe dictates the 2R in the denominator. At the antenna jack and across a 50 ohm load, how about Vrms^2/50 ?

I like to use the scope across a 50 ohm dummy load and use
((Vp-p/2.8)^2)/50

Whats your favorite formula?

Subject: [AT_Sprint] Power Measurement

Hi All,
To properly adjust my output filters on my ATS3b band modules, I've made a pretty accurate dummy load.

I am planning on using the diode detector shown in Figure 7, on page 146, of "Solid State Design" to measure RF Voltage at the antenna jack. Seems to be a fairly accurate way to measure output power at 5 Watts. Any comments?

Note the output power is computed by V*V/(2*R).

Steve, W2MY

I am not too sure of the math, but I think V*V/2R makes sense. The peak detector measures peak DC Voltage. So RMS is .707. Square that for V*V and you get .5, and that makes the 2 in the denominator.

Does that sound right?

Yep, didnt realize it was a peak detector. Several ways to do the calculations, the most difficult part is obtaining accurate voltage measurements to work with.

I had no trouble centering the LO in the filter passband, but when I got to Step 5 the signal at the earphone is clipped except when shifted way off peak. Of course the clipped waveform doesn't change in amplitude as you adjust CT1. I am using Visual Analyser and it does have a 'signal strength' scale (vertical bar graph) that showed the signal increasing, then staying the same and then decreasing, so I was able to guesstimate where centre (max amplitude) was.

Is this clipped waveform what others find when they're at this setup stage?

I had it fired up on 40M today and the receiver is very sweet. I have only measured output at about 1.9 watts (9.5 volts RMS across 50 ohms) with the rig's battery reading about 8.5 volts, but I am not sure that my rf probe is reliable. I built this probe today (http://www.io.com/~n5fc/rfprobe2.htm) , but don't have any way to check it out yet.

Now to build all the band filters (30M is done). Then its time to put it in the box.

wrote:

Stephen,

Congratulations on getting your rig working!

Step 5 and 6 center the audio frequency - the beat frequency
determined by the IF and BFO - in the AUDIO passband. The ATS rigs
have a very peaked audio response. The audio response is designed to
sharpen the selectivity of the receiver.

If you sweep an audio signal through the ATS-3 audio passband, it
will show a significant peak near 600 Hz. Steve Weber says the Q of
the headphone amplifier/filter U3b is about 5. You need to take your
audio output from the headphone output line for any measurements or
adjustments relating to the audio peak frequency.

I used a wonderful old HP-400D AC VTVM for all my audio tests on my
ATS rigs. There is a very distinct peak near 600 Hz, and any
clipping is minimal. The rig does have some audio AGC/limiting, but
the audio filtering of the last stage helps to clean up any
distortion products.

If you're connected to a computer soundcard, and you're seeing a
flat, clipped response, perhaps your signal level is too high for the
soundcard, and clipping is occurring at that level. Try attenuating
it with a pot.

Instead of using a computer with many additional variables, I'd
suggest using a scope on the headphone output, or an HP400D meter, or
both (what I did). Here's a key point: the headphone op amp wants to
see a low-Z load similar to what your headphones are. So go ahead
and connect your favorite headphones, or a resistor, to the headphone
jack for any tests you do. I found that the frequency of audio
resonance shifts slightly depending on the audio load impedance.
This is an effect - but not really a problem. You may notice it on
the air if you use a headphone volume control. When you turn up the
control, the load Z shifts downward, and the frequency response
shifts upward. It's about one click on the UP-DOWN buttons. You'll
hear it if you're aware of audio frequencies.

I found that the audio peak on my ATS-3B shifted from 590 Hz with a
high-Z audio load up to about 640 Hz with a 10 ohm resistive load.
The Q also increased as the load decreased, so the audio peak is a
little sharper with the volume turned up. Your results may vary,
since headphones are complex, but there are effects.

In the end I shifted my headphone amplifier's peak response down a little by increasing C22 and C23 a bit. This is an easy mod if you like a lower BFO tone. Remember to redo the BFO adjustment in steps 5 and 6 if you mess with the audio peak.

If your receiver sounds OK, it's probably working well. If you test it with a sig gen, and you run the RF input up, the audio should start limiting when the RF input gets above about -80 dbm. This assumes that your RF filter modules are peaked really well. The limiting level is LOUD with efficient headphones, so a volume control is a good idea.

There's more stuff on these subjects here - please use the SEARCH feature to find interesting stuff in our previous posts, and have a look in the FILES and PHOTOS. I'm pretty sure I posted an audio plot in there somewhere.

No doubt the ATS-3 receiver is one of the best simple CW receivers ever designed. You can hear less than 0.1 uV with it if you work with the filter modules to be sure they're really peaked.

Hope you enjoy it as much as I do.

Hi,

I am working on a through hole version, same 2.7" x 2" format so fits in an altoid tin with locally available transistors and diodes, all either Mouser or Digikey variants. I am using ExpressPCB to create the PCB layout which means Blue Press n Peel film means I can etch my own. I hope to have it ready for FDIM 2008.

A few have looked at reworking the NB6M Miniboots PA for a while and Chuck Carpenter has a nice little PA out soon that is using a modern alternative for the IRF510 MOSFET which should run cooler and more efficiently, last I read it should be out about the time FDIM 2008 comes around. Note that JN1GLB, Makota-san is rekitting and you can order from him directly. 8500 Yen is about £41 or $80

3035. Re: [AT_Sprint] Centering the Beat note (was (unknown))

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-07 17:35:24 UTC
From: Stephen Wandling
Topic: 3030 Message: 3035

Carey,

Thanks for all of the info and suggestions. Two of your suggestions I had already tried. I lowered the microphone input to the sound card to almost zero and the clipping remained. I also used a splitter on the phone jack so I could listen while I did the adjustment, so that should have brought the impedance down to where the filter was happy.

I don't have a scope or HP400D, although I do remember using one when I worked for Lenkurt Electric in San Carlos, CA in the 60's.

My gut feeling is that there is clipping going on in the ATS during this test. Whether this is a result of the level of the test tone generated for the test being too high, or a problem in the circuit, I don't know. My hearing is old and mushy, but the rig sounds pretty good with on the air signals.

I was on the SKCC (Straight Key Century Club) sked page and announced I was sending a CQ on 7062 and a guy in Santa Fe, TX gave me a 229. He said he only knew it was me because he saw my posting on the sked page. No QSO, but this is with the rig laying naked on my bench, connected to the ATU with 16" alligator clip leads, and a dying 9V battery. I think the battery voltage was about 7.5V according to the ATS. I haven't worked at peaking the filter boards yet. I want to get a good 12V supply running first. I don't want to peak them on 9V and then have them set too hot for 12V.

I will do some searches, but the 12V limit is confusing to me. Steve talks about using a freshly charged gel cell, but won't they be higher than 12V? I know guys like N0TU use Li-Poly batteries at 11.1V. I wonder why Steve didn't put in a 12V regulator?

You mention that you "shifted my headphone amplifier's peak response down a little by increasing C22 and C23 a bit". Do you recall how much you shifted them?

Thanks again.

wrote:

Stephen,

I can't be sure about your clipping problem. I remember that the rig can be set up just by ear - you just set the BFO so the audio sounds like it's at the center of the audio passband. I think doing it by ear would be better than trying to use a digital interface, etc.

Be sure to search the messages here for other ideas - some have used computers with a program called Spectrogram, I think, to look at the audio passband of the ATS rigs - they have had good results.

I believe you should follow Steve's alignment instructions so that the rig ends up transmitting on exactly the same frequency it receives on. The DDS is used to set receive and transmit frequencies, as well as RIT, and the setup routine in the manual makes sure that the firmware is programmed with the correct offsets so everything comes out right.

You're right that you should do all your alignment and adjustments with a regulated supply. You're also right to peak the filter modules with a 12V supply is you plan to run on 12V (ever).

Yes, a peaked lead-acid battery might be above 13.0V, depending on the chemistry and how long it's been off the charger.

I use three Li ion cells and they measure about 12.4V right after charging. The load of the rig during transmit, along with a polyswitch, a protective circuit in the pack, wires, connectors, a switch, and the protection diode in the rig reduce the final voltage somewhat. Lots of people here have suggested putting a diode or two in series with a 13V battery. It would be easy to put a switch in for when the battery's freh and for when it's down. Reistors work OK with this rig also.

Steve didn't put in a regulator because there isn't room, and it isn't desirable for most of us. When we go portable with a small battery, we don't want to lose any energy in a regulator. The rig is tolerant of voltage sag and weak batteries, so it will continue running until almost all the energy is used. A regulator would subtract from the available energy. You can always add one externally. The QBSA has an adjustable voltage regulator - it's fine - an LM317T. Steve designed it to top out at about 11V, but some of us tricked it to go up to 12.0V. I posted this here some time ago. The QBSA and the ATS-3 rigs make a really nice setup for

home use.

It's easy to find HP400's at hamfests. They are common and usually go for $10 around here. Not very energy-efficient, but work well. An ordinary AC voltmeter, DVM type, will work fine at 600 Hz. Try that. Analog AC meters are fine too - Simpson 260, or whatever you have. I agree that if you can't see the peak as you adjust the BFO trimmer, you do have clipping for some reason. I used a scope for those tests and did not see clipping. If you have clipping in the audio chain, you'll probably need a scope to debug that, unless you can inspect and find the problem.

I made a big mistake in my previous message, where I mentioned C22 and C23; those are the original wrong component designators in my manual; the designators on the PCB for my ATS-3B are C20 and C21. These are also C20 and C21 on the revised schematic. I raised C20 and C21 by adding 560 pF in parallel with each. This has a small effect, since C20 and C21 are increased about 5.6% (they are both .01 uF or 10,000 pF). I'd say don't bother unless you really care about your audio frequency.

Now I'm going to admit some non-understanding here, and hope someone else knows the answer:

If we set up the audio peak on an ATS-3B at 400 Hz instead of 600 Hz, by increasing C20 and C21, and then re-adjusting the BFO trimmer, would the rig still transmit and receive at the same frequency, on all bands? Remember that the rig's LO is on the high side of the IF on 80 meters, and on the low side on other bands. Does the audio tone have to be 600 Hz for everything to work right? Am I stupid for adjusting my audio tone down a little? Who knows for sure (Steve knows)? Mike?

Some day soon I'll check to see if my ATS-3B actually receives and transmits on the same frequency on all bands. This is a hassle, but with a counter and a sig gen it's not too hard. It can be done with another rig (modern rig) and attenuators also. For casual operating an offset is no big deal, but for DXing and serious operating the rig needs to be spot-on.

Lots of great questions Stephen - sorry I don't quite have all the answers tonight.

Yes it should be fine only your sidetone will not be 400Hz. I like my sidetone to match the offset, to make it easier to zerobeat.

With my firmware you can change the audio sidetone to a lower frequency with out having to modify hardware. With Steve's it will be a little harder because he uses the timers a little differently than I do.

You can alter the final op amp in the audio chain to be a lower center freq than 600Hz or even change it to a low pass filter.

As far as accuracy on all bands: If you follow Steve's or my calibration procedure's you can be spot on all bands. Once you get the DDS "fudge" factor you are good to go for all the bands. You should be able to get within 10Hz at 10MHz which would make you 20Hz off at 20MHz. Pretty good if you ask me.

3038. Finally adjusted the band modules

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-08 02:22:01 UTC
From: Steven Pituch
Topic: 3030 Message: 3038

Hallelujah!
I am so happy. I may have finished my ATS3b. Here are my numbers for 12.00 Volts:

BAND	Volts PWR	Amps
80M	22.6 5.1	.634
40M	22.6 5.1	.668
30M	23.4 5.5	.745
20M	23.1 5.3	.741
17M	22.6 5.1	.753
15M	23.2 5.4	.728

Some of you may recall that I had previously used a dummy load that was 13% high and my OHR WM-1. This turned out to be a bad combination. I was approaching 1 Amp just to get "5" Watts which was really closer to 7 Watts. Its a tribute to the design in that I didn't have a melt-down.

I built a simple peak detector, and a precision dummy load. I put them both in a plastic box with binding posts for the voltmeter and a bnc jack to connect to the ATS3b. Once it was built it made taking accurate power measurements very easy. Just square the DC voltage reading and move the decimal point over two places: (V*V/(2*R). This tool is a keeper. I wonder why Doug Hendricks hasn't made a kit of it.

I need to post a schematic of the tool and some photos. It is in Solid State Design on page 146, Figure 7. I will also post my adjustments to each band modulw for reference for other builders.

Thanks everyone on the list for the help. I was ready to give up several times thinking that I had terminally damaged the kit while building it. However, I had very few errors. It was actually a relatively easy kit to build.

I am looking foward to bringing the ATS3b, SLT tuner, and my Jackite 31' pole to a picnic this Saturday and operating outdoors.

Does anyone use dropping diodes to reduce the voltage from a gell cell? I would think a 1 Amp diode with a .6 volt drop would be ideal.

Steve, W2MY

Carey,

Once again, thanks for the great response.

I did initially try to set the BFO by ear, but only heard the change in pitch, but not in amplitude. There was no 'peak' as I was expecting.

I can try to do some tracing, but I need to know what's happening when we're doing this adjustment. Apparently, the rig simulates a CW signal coming in, but I'm not familiar enough with the circuit to know how this was done. (Where are the tubes?? :-))

Just had my first QSO on this rig on 80M. Built the 80M filter board this afternoon, but the receive was weak and CT3 had no effect. I have now confirmed Steve's statement, that if you mix up the 4 wires on LF3 you will have poor reception. Not having any more 32 ga wire, I removed the coil, sorted the wires, added extensions and put it back in. I live in the bush here and will see if anyone sells 32 ga in Kamloops tomorrow. I will have to wind a new coil as the extensions provide a great opportunity for shorts. My last 9V battery was down to 7.2 by the end of the QSO.

This leads to another question: each time I passed it back, the CW tone was down and I had to tune down one click to get it right again. Is this a result of the dropping battery voltage, as I presume it is?

I have an old 12V 7Ah gel cell on the charger now and will see what the rig does with more juice.

I have to get my head around this sidetone issue, because I want to be sending and receiving on the same frequency. I noted Michael's response to your "non-understanding" below, but I'm still unclear as to what's going on in the rig. He said your sidetone would not be 400Hz, but if you tune so you are hearing 400Hz, the question is what is the offset, right?

You mention 3 Li-Ion cells at 13.0V. Is it the Li-Poly cells that are 3.7V per cell, giving 11.1V for 3 cells?

I think I need to take a break from this for today. Thanks again.

--- In AT_Sprint@yahoogroups.com, Stephen Wandling <swandling@...>
wrote:

Stephen,

I did some measurements tonight and this is what I found for my ATS-
3B:

1) The audio peak is at about 610-620 Hz now, with C20 and C21
increased by 560 pf parallel caps. This peak was checked with
headphones having a parallel impedance of about 30 ohms. With a
higher Z, such as when the headphone volume is reduced, I have an
audio peak in the 590-600 Hz range. So I'm not tuned for a lower
pitch audio tone at all. Probably C20 and C21 are just a little on
the small side of their .01 uF nominal value, so the parallel caps
just make the circuit work as designed.

2) The transmit and receive frequencies measure within 20 to 30 Hz of
each other at 3.56, 7.04, and 14.06 Mhz. I used a counter, a crystal
oscillator, and some attenuators to compare the input and output
frequencies of the rig. Since the rig tunes in 50 Hz steps, and the
audio peak is broad enough that sometimes two steps are roughly equal
to the ear, this is fine. On all three bands, when listening, the
error was such that the second, almost equally loud frequency step
next to the apparent peak step was on the other side of the measured
transmit signal. 80M has no more offset than 40M or 20M; if anything
80M is almost spot-on. So there's no problem with more offset when
the LO's on the other side of the signal, as on 80M, on my rig.

3) I would have to spend a lot of time with more and better equipment
to get a better alignment. The receive-transmit frequency match is
better than most QRP analog rigs can achieve with ordinary
components, separate oscillators, and multiple temperature drifts,
particularly after some knocking around.

4) Since the ATS rigs tune in 50 Hz steps, you're not going to get
closer to the other station's frequency than the buttons allow. With
good ears you can always tune within 25 Hz or less, with an
additional error due to alignment.

5) So we should do our best with the alignment. Steve has provided
an excellent method to minimize frequency errors, while making the
procedure simple and reasonable.

6) My rig has been on a bunch of winter campouts and backpack trips
since I aligned it several months ago. I was really pleased to see
my errors coming in so tight. Of course, there's always room for

improvement in specs and adjustments, but not with my equipment. My test gear is only about one order of magnitude more accurate than this rig - as near as I can tell - HI!

7) I think it's worth checking the audio peak frequency with YOUR headphones plugged in, and a counter connected - if it's not close to 600 Hz, the T-R offset may be worse on 80 than on other bands, or vice-versa. This is the issue I'm not real clear on - but with 600 Hz you'll be right for sure, since Steve says that's the design peak.

8) You can ignore all this stuff if your rig works OK.

Stephen, my rig does have a somewhat clipped sound - actually a clipped and filtered sound - when I run the RF input up into saturation. Both my ATS-3B and ATS-3A sound about the same (my "A" doesn't have any extra caps on the output filter, and it's peaked near 600 Hz). All measurements above were done with the RF input reduced to a low level, maybe about -100 dbm, so I could hear the audio peak without any AGC or clipping effects.

The real trick would be to in the spirit of the original design come up with a class E or more likely (my idea) a class E/F odd hybrid amplifier. I made a couple of quick sketches and calculations into this effort, but am too busy at work to do any real designing, (plus i'm leaving for Tokyo in 7 days) It on my todo list, but based on power densities you should be able to get 50watts out of an altoids tin with a modest heat sink.

Yes, a good feature. I ordered one a couple of weeks ago from Norcal, and hope to receive it in a few weeks. At $7.50 it seems to be a good deal. I didn't want to wait so I built my own.

I posted the schematic here:
http://www.pituch.net/p/Steve's%20Page/Radio/ATS3b/ATS3b.htm

> I need to know what's happening when we're doing this adjustment.

Hopefully I have this right:

When adjusting the offset, the DDS is programmed to produce the
IF frequency which is then fed to the mixer to put it into the
crystal filter (defaults to 4.914700MHz). The tune-up and tune-down
buttons allow this frequency to be adjusted until the signal is
in the center of the crystal filter's passband. The resulting
frequency becomes the actual IF frequency and the offset applied to
the desired receive operating frequency to cause the DDS to produce
the appropriate LO frequency.

The second step is to adjust the BFO trimmer to cause the BFO to
oscillate at the actual IF frequency offset by the sidetone frequency
(hard-coded at 606Hz in the ATS-3B). The result is that the audio
frequency of the received signal matches that of the sidetone, making
it easy to zero-beat received signals by comparing the sidetone
frequency to the received audio.

> This leads to another question: each time I passed it back, the CW
> tone was down and I had to tune down one click to get it right
> again. Is this a result of the dropping battery voltage, as I
> presume it is?

I doubt it has to do with battery voltage. The BFO and 60MHz
oscillator run off of regulated 5V and 3.5V respectively. Assuming
that the other fellow wasn't also stepping down in frequency during
the QSO (given the amount of drift, this seems a real possibility),
I would suspect thermal drift of the BFO or the 60MHz oscillator.

> I have to get my head around this sidetone issue, because I want to
> be sending and receiving on the same frequency.

As long as the BFO trimmer is adjusted to produce a tone that matches
your sidetone, you will be zero-beat when any received signal's
tone matches your sidetone frequency. If you decide to use a
different BFO offset, say 400Hz, you won't be able to use the
sidetone as a reference tone unless you modify the code to produce
a 400Hz sidetone. Of course, you could always use an some
independent external reference tone.

> Is it the Li-Poly cells that are 3.7V per cell, giving 11.1V for 3
> cells?

Fully charged, the LiPo cells put out about 4.2V each.

I was thinking I needed to try to better clarify my
last message and I think Dave did a great job. Thanks
Dave!

Would like to emphasize that changing the last op amp
(C22/C23) will only change the best audio bandwidth
center freq. Your sidetone will still be 606Hz. From
my firmware you can choose the following discrete
sidetone values:

; 27 -> 606Hz default ATS3B
; 28 -> 585Hz default ATS2,3,3A
; 33 -> 496Hz close enuf to 500Hz
; 37 -> 442Hz for the musician's
; 41 -> 400Hz lowest we dare go606Hz default ATS3B
; 28 -> 585Hz default ATS2,3,3A
; 33 -> 496Hz close enuf to 500Hz
; 37 -> 442Hz for the musician's
; 41 -> 400Hz lowest we dare go?

If you change the sidetone via the firmware you should
also change the final op amp to handle it more
effectively. On my ATS3 I run 400Hz sidetone, because
I have changed the last op amp configuration to be a
low pass filter vice a bandpass filter. (More info at:
< http://w1mt.qrpradio.com/filter.html >) Note: that
the bandpass op amp mod is the only one that would be
applicable for the 3b if someone was so inclined.

Mike,

Thanks for this information, and for your previous, very clear answer to my question. Dave did a nice job with his clear explanation of the alignment.

After a little reflection, I remembered that the ATS-3 BFO is a separate oscillator running in the second SA612. It has no direct connection to the DDS. The IF is the same for all bands. The fact that the LO is above or below the IF has no bearing on the BFO or the audio pitch - but it does affect whether the pitch goes up or down when we tune up and down. So I agree that setting the audio tone to 400 Hz or whatever has no affect on whether the transmitted and received RF are at the same frequency. That's a function of the alignment.

Since most of us match the sidetone to the received signal's pitch, and the ATS rigs do this at 606 Hz, we should consider using your firmware if we choose to use a different audio pitch in our rigs.

I'm curious if you improved the sound of the receiver with your changes. Going down in pitch is a personal thing - but it does enable the low-pass idea to work really well. I have an Idiom Press SCAF-1 filter, which is a very strong adjustable low-pass, and I like the way it works with some other rigs I have.

Thanks again to all of you!

Steve,

I have one of the Norcal surface mount dummy loads, and I think it's a great product for QRP work. The detector circuit is good, people have checked it against calibrated instruments, and the impedance is very close to 50 ohms across the HF bands.

Your HB load looks cool - what is the resistor hidden under the epoxy???

Years ago I thought I'd make a dummy load, so I took a bunch of 2.2K carbon comp resistors and wired enough in parallel to read 50 ohms. Only later did I discover that the capacitance of those "non-inductive" resistors adds up when you have many in parallel, and such loads are reactive at HF and VHF because of the capacitance.

The Caddock resistors are very good at RF, and 50 ohm values are available in sizes like about 20W. These are in TO-220 and similar packages.

Metal oxide resistors (MO) are pretty good also, and very inexpensive. I use these in the Dan Tayloe LED SWR bridges in my BLT's, and they're just fine. Two 100 ohm 3W MO's in parallel is a good cheap 50 ohm load, if you keep the leads short.

I have some microwave loads with N connectors that I use for "standards". The MFJ-259B says they're perfect. I check other stuff with the MFJ-259B.

I ruined the calibration - probably fried the detector diodes - of the MFJ-259B because I connected it to an antenna. Yes, I connected my SWR analyzer to an antenna and it damaged it. Common mode signals from a moderate-sized wire antenna (inverted L) will damage an MFJ-259B. I was not transmitting. There is enough voltage on an antenna to ruin an analyzer - 60 Hz AC hum from HV power lines in the back yard, RF from a local AM BCST station, static charge from wind, rain, snow, and clouds, etc. Don't ruin your analyzer. The manual warns but not enough. Don't connect to a large antenna wired up for common mode !!!

I still think it's a great tool for checking out measurements and gear - but it's really delicate.

Enough for tonight - sorry to shift subjects, but it may save one of you from the humiliation I feel!

Steve,

Your patience really paid off! These are NICE numbers all around.
Quit while you're ahead!! Nice work! Awesome.

Your diode idea is fine. A 1N4001, 4002, etc. will drop about .6
or .7 volts at 1A. Use 2 if you need 1.2 to 1.4V, etc.

Use a schottky diode like 1N5819 is you want .3V drop to fine-tune.

Good luck with your rig on the air. Usually it's a pleasant
surprise. With a good antenna the rig will surprise you and the
other guy across the country!

Thanks to Michael, Dave and Carey for all of this good information. The pieces of the puzzle are beginning to fit into place. This is what I needed. I find it nearly impossible to run a "black box" system where I don't know why its doing what its doing when I do what I'm told to do to make it do what I want it to do.

Carey mentions the issue of "whether the pitch goes up or down when we tune up and down". To confirm, on 80M I had to tune Down to get the received tone to move higher in pitch. Is this correct?

The clipped signal during the BFO frequency adjustment still concerns me, but the receiver seems as 'hot' as my IC706 (my test equipment), so something is working.

On the topic of filters, I have the NEQRP Scaf filter which I love, or more correctly, my ears love. It is a bandpass configuration and can clamp down to about 65 Hz, which is where I tend to run it. I don't like hiss or lows. I also appreciate the crystal filter in the ATS3-B, which is something the IC706 is currently lacking.

wrote:

Stephen,

Yes, 80M is the band that is different. This is because the local
oscillator, the DDS that you tune with the buttons, is ABOVE the IF
(crystal filter frequency at about 4.91 Mhz).

Be sure to read Steve Weber's theory/circuit description in the
manual, and spend some time studying the schematic of the receiver.
The most difficult thing to see is how the two drawings connect
together and to the filter modules. It would be nice to have larger
functional drawings showing the whole thing in one view.

I also have a NESCAF, and it works well - I have used it with the
ATS3 rigs, but I think it's overkill. I think that my ATS3A and B
sound better as they are. They're narrow enough for me. The noise
level is pretty low also. In a quiet location, away from
development, you can appreciate the low noise of the ATS3 rigs.

Good night!

Hi Carey and All,
I used 8 Radio Shack 100 Ohm resistors. I believe they are metal film. I also used four 1 Ohm 1/4 Watt resistors in parallel to add a little to it. With my two DVMs I am getting about 49.9 to 50.2 Ohms.

I just got the Norcal dummy load in the mail and it looks very nice. I would like to put two binding posts on a box for the DVM.

Also I noticed that it and the Elecraft dummy load only have one cap and one diode, where the design I used also has two caps and a 1000 Ohm resistor, I am not sure what the advantage is for the extra parts.

I had a 40 meter vertical loop in the trees once and on a windy day wanted to check continuity. I was surprised when I measured a considerable current across the end of the feedline.

3056. Adjusting the LO offset

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-12 18:10:21 UTC
From: Dave
Topic: 3030 Message: 3056

After thinking things through to make my previous post, I also realized that the way I was adjusting the offset was not quite right. I had not considered how steep the edges are on the crystal filter and had been looking for only a slight drop in the signal at TP2 as I stepped the frequency up and down. Having now realized that the edges of such a bandpass filter are usually specified at the 3dB-down points, I went back and readjusted, stepping down and up until the waveform's peak voltage was about 70% of that near center. At those points, the signal's amplitude changes significantly with each step. I found that I had originally set my ATS-3A about 50Hz low and the ATS-3B about 70Hz low.

After readjusting, both ended up within about 20Hz of 4.914800MHz (calculated from the DDS configuration values). The A's filter appears to be about 370Hz wide and the B's filter about 320Hz wide.

I reported here that on my first QSO with the ATS3-B on 80M, each time the other guy came back, I had to hit the down button to raise the tone to a readable frequency. He was using separate boat anchors and might have been following me down, I don't know for sure, but we had a pretty long QSO.

Tonight was my second contact, on 40M. But, tonight the other guy made a long transmission and I had to hit the down button many times, (I kind of lost count) to keep the received tone the same. It just kept dropping every 10 or 15 seconds, But, this time, I used RIT, as I imagine I should have on the first contact. When he signed to me, I made a short transmission and then sent it back to dead air. He was gone. When I finally found him (up a couple of Khz), he was sending 73 and SK. I gave him a call but no response.

Something is obviously not right with the rig. I was on a 9V battery and the rig showed a voltage of 8V on startup, and about 7.7V when I lost him, so it shouldn't be a voltage problem. It's almost as if on the 80M contact the rig acted as though it was in RIT mode and tonight in RIT mod it acted like it was in 'regular' mode. (But I would have to contact the 80M guy to see if he noticed my frequency shifting or not.)

Definitely a mystery. I can't think of more to add right now, but if anyone has a question or an idea, I'm all ears.

From: Stephen Wandling
Topic: 3058 Message: 3058

After writing the report below, I was reading some emails with the Bee buzzing in the background. After a bit, I realized that the guy I was listening to had had about 4 QSOs with various people and there hadn't been a hint of shift in his frequency or theirs.

Curiouser and curiouser.

wrote:

Stephen,

This rig is controlled by the reference oscillator, a stable crystal-
controlled unit, and it runs off a voltage regulator in the rig.
Your battery shouldn't be a problem, but using a stable voltage is a
good idea for troubleshooting.

Stability in receive and transmit normally is about the same, since
the DDS is controlled by the same reference oscillator all the time.
Any thermal drift gets worse as the rig transmits and gets warm,
since the heating is much greater when transmitting.

On 80M these rigs are usually more stable than on the higher
frequencies, so your experience is not typical at all.

Two easy things to try:

1) Listen to a known stable signal. This could be another ham rig on
a dummy load - it should be a synthesized rig known to be stable, not
a VFO rig. Your signal could be a crystal calibrator or other
crystal oscillator, the kind most of us have had around for years.
It could be a synthesized signal generator, if you have one.
Whatever you use, warm it up for a long while so its reference
oscillator stabilizes. All these signal sources have some drift -
but if you minimize it, you can get a feel for the ATS rig's drift.
If you have a counter, warm it up too, and then measure the source to
make sure it's not drifting much.

If you have a VFO and a counter, or a VFO rig and a counter, you can
just measure that signal while keeping it peaked in the ATS's
receiver (match the sidetone).

2) Measure the frequency of your ATS rig's transmitted signal with a
counter (warmed up) while on dummy load. You'll need some kind of
attenuator to present the correct level to your counter input- be
cautious not to damage the counter. Use the minimum level that gives
a stable count. Don't hold the key down, unless you want to do a
harsh heat test - just key the rig every few minutes while it runs in
receive mode, and see if it moves much.

Try your tests on several bands if possible.

Also try to check your oscillator and counter, or sig gen, or
whatever your rely on, back to WWV's signal just to be sure your

gear's stable and any drift is minimal. Ideally you want something that stays within a few Hz of WWV for an hour or so. A low-power solid-state crystal oscillator, operating on regulated power, shielded, and at a stable temperature can do this if it's solidly built and warmed up.

You can use secondary standards to check against WWV and then to check your counter, or your rig's VFO, or whatever, so you have some control of imperfect equipment. I have an old TS-520S, and it has a crystal calibrator, which can be used as a secondary reference, to help deal with the drift of the VFO in the rig.

Even with no counter, I could warm up the TS-520 for an hour or two, set it to a convenient frequency that the ATS rig could hear, and also right on top of one of the TS-520's crystal calibrator points, such as 7025 KHz, 3550 Khz, 21050, or whatever. So I'd carefully match the TS-520's VFO to the calibrator, listen for the frequency with the ATS rig, measure and record the frequency with the ATS's readout; then repeat ALL the steps to make several measurements over a longer period of time, like 30 minutes, to measure the drift.

If you don't transmit, the ATS will stay cool, and unless something's wrong, I doubt you'll see much drift. Since I haven't noticed much of an issue on the air, I've never actually done a drift test on my own rig, but there are lots of ways to do it with whatever gear you have. Somewhere in the setup you'll need a stable oscillator that you have some confidence in.

If you have a known good counter, with its own frequency reference fully warmed up, checking your ATS rig is easy. Since so much of the rig is digital, almost everything points back to the reference oscillator if there's a problem. With a scope, probe, and counter you can check the reference oscillator. It's also very easy to check the DDS frequency at pin 20 - put the probe on R16 - this is the "B" signal, essentially an unused RF output of the AD9834. Some of us use this signal for the QBSA to measure. The QBSA is an external counter and frequency display.

Since my rig doesn't show much drift on my QBSA, I've never done more serious measurements. I have had QSO's where I had to chase the other guy with the RIT, but he was running old tube gear, or the ATS rig was sitting in the sun outside, or both.

The ATS rigs are much more stable than a lot of signal generators.

My ATS-3A can be tuned across some of the the band edges, and on that rig it's easy to go directly to WWV at 10.000000 Mhz and listen for any drift. It also transmits there, making it easy to use the rig as a transfer standard. Unfortunately it tunes in 50 Hz steps, or it could be used for really accurate transfers. My "B" won't go across the band edges...Steve fixed the code.

Another easy method for checking your rig is to schedule a QSO with another ham who has a relatively stable synthesized rig. Make sure he's warmed up and hopefully he has a TCXO reference and a high-class rig. After a half hour or so you should have a handle on any drift you may have.

The ATS rigs don't have a TCXO, and I'm sure there's some drift when running from a cold start, especially at sub-freezing temperatures. I've never been in a position to measure this drift when I've been out camping in the snow. Some day I'll do more formal measurements just for fun.

Wonder if other ops here with nice test gear have done any drift tests?

What kind of 9v battery? If it's the small rectangular
"transistor" battery then try something more
substantial and report on the results. These batteries
cannot supply the current necessary for transmit and
that may be the cause.

You might try measuring your voltage with key down
into a dummy load just to confirm.

Michael,

Yes, it is the small 9v battery. Its voltage drops about
1V on key down. The voltage across the dummy
load drops about 0.05V RMS during a 3 second key
down.

I've been given a monster (70 lb) commercial (Motorola)
rack mount 13.8V 25A power supply, with a 9.6V
regulated output as well. I will install this soon and this
should provide an appropriate supply voltage.

I have monitored the transmission frequency with my
IC706 and the ATS running into a dummy load. On
long keying sequences simulating a QSO, there was no
perceptible change in frequency.

As I noted in my addendum last night, I have listened to
other stations operating over a period of 1/2 hour and have
not noticed a change in pitch.

I will see how things are when I have better power.

The more I think about it I don't think a low 9v battery will do what you have described.

I think that the other end of your qso is chasing you then you are chasing them and so on. This will happen when move freq to match your sidetone and your offset is not equal to your sidetone. Rit is one solution, it might be worth rechecking calibration as well.

Mike,

In some tests today, with a fairly depleted 9V battery, I noted that on a 3-4 second key down, the supply voltage dropped below 6V. That made me think about the 'reset' that Steve inserted for when when the internal 3.5V voltage dropped a certain amount below 3.5V.

But, I perceive the shifting when I am listening, and all voltages appear to be fine then, even with a 7V supply voltage.

Chasing was my first guess, and it may be a correct one, as both stations I have contacted are boat anchor equipment. I contacted the first guy who replied "when you are using 50+ year old gear, drifting is a matter of interpretation". He went on to say that he usually retunes his receiver on each go around. He wasn't "aware" of any drifting on my part. The more recent contact has not yet answered my email.

That is the similarity between the two QSOs. The difference is that on the second one, I used RIT. On the first one I just hit the Down button when he started sending each time. Plus, on the second QSO. I had to hit the Down RIT button every 15-20 seconds or less during a 2 or 3 minute transmission.

Assuming the second guy stayed on frequency when we lost contact, I was 2-3 Khz down when I made my last transmission.

If #2's VFO was drifting, then my correcting with RIT should not have created any problem. Its almost like my RIT and what ever you call the non-RIT mode, are reversed.

I'm now running on a massive power supply at 9.95V 'regulated'. On key down the voltage drops to 9.64V. This gives me about 3W output. I haven't started the filter tweaking yet.

I guess I just have to make some contacts and see what happens.

Thanks for everyone's ideas and suggestions.

wrote:

Stephen,

Congratulations on the larger power supply! Please read my recent
long post if you have the patience.

I agree with Mike that one station chasing another is a possibility.
Some operators don't know how to match another station's frequency,
or they just don't do it for other reasons. The result is a series
of corrections each go-round.

You can tell when RIT is operating in the "B" by the lit decimal
point on the display. You do need to be careful of whether RIT is on
or not, especially when you find one of those operators who keeps
coming back off frequency. I've screwed up because I thought RIT was
on and it wasn't!

Believe it or not, there are folks out there who actually zero beat
your signal when they call. They think they're supposed to do this.
In the QRP world, there are many ops running DC receivers (direct
conversion) who don't or can't come back right on frequency; and
there are quite a few with better QRP rigs that haven't been aligned
right, so there's an offset between their receive and transmit, only
they don't know, because they haven't checked it.

I think you can gain some confidence if you don't have drifting QSO's
with the guys running the more modern rigs, or if they stay put while
you monitor them. Tube gear does drift as it warms up, and some ops
don't warm it up enough before jumping on the band. Several KC of
drift is no problem for a tube oscillator coming up from cold.

For portable work get a battery rated at least 1000 maH. Lithium
rechargeables or NiMH are great. You won't be disappointed with 8 to
10 NiMH AA cells, although 10 cells is well over 13 volts with a
fresh charge - need a diode or two to drop that initially. 3 size
18650 Li ion cells, or 3 lithium polymer cells, will provide more
QSO's than you can handle. Even 8 AA alkaline cells will run the rig
nicely for countless hours.

I don't know where all this 9V smoke detector battery stuff got
started. Yes, the rig will run for a while in a sprint with a fresh
9V alkaline battery, if you keep the transmissions short, but what's
the point? That's not normal operation - that's a special event.
For pleasant, relaxed operation, at home or in the field, you need
stable power, with plenty of reserve for cold weather or whatever.

The ATS rigs allow you to provide that depth of power without
carrying much weight. My 3-cell Li ion 18650 pack, with over 2 AH at
about 11V, in a plastic box, with a series resistor for tuning, a
slide switch, a protection PCB, a polyswitch, and a connector weighs
7 ounces. An alkaline 9V battery weighs 2 oz. I know which one I
want on a serious radio hike or campout...

Carey,

Well it may well have been a case of chasing each other. I
just completed a long local qso with a guy I know who has
a digital rig. No drifting, shifting or other machinations were
observed.

But, it still bothers me that on the 40M event the other night,
I used RIT (the decimal was on) and yet I ended up way below
him when I came back. He still hasn't answered the email.
Maybe I got his email wrong off of QRZ.

Thanks for the battery info. I will be putting together a NiMH
pack until I can afford the LiPo. I've just rebuilt and modified
my BLT to it will cover 80M, and will be building a tuner for
an EFHW wire, probably for 20M. Both of these tuners (will)
have an absorption SWR circuit so the ATS will not strain
anything during tuning.

I can't work much 20M from this box canyon where I'm located,
so I am looking forward to some excursions up to the rim and
hearing how one of my favourite bands is doing!

Keep an ear open for me on the bands.

3066. Dead Receive with 12v??

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-14 10:15:17 UTC
From: Jim Fraser
Topic: 3066 Message: 3066

I had just completed putting my 3B into its enclosure and thought I would listen around a bit this evening. However to my surprise the receiver was dead, no hiss, no static, nothing. However, the transmitter works fine, and the sidetone and button audio responses work.

So, I went and checked the voltages in the receiver as per the table in the documentation and all measurements were in tolerance. I buzzed the connections from the band module. I was running from a battery pack of 8 AAs. I also tried running from my Jameco wall wart rated @ 12v, 1000ma with no luck. After studying the schematic for a bit I thought I would try hooking up my QBSA to the rig. It worked...what the #$%@!

The battery voltages reported by the 3B were 11.9v for the batery pack, 12.3v for the wall wart and 10.4v for the QBSA. Does anyone have any idea why the receiver mutes at 12v???

By the way the voltage chart for U5 Audio AGC is incorrect. It should be:

```
|------|
|5 1|
|4
|3
|------
```

HI Jim and All,
I may have a related problem with my new 3b. It seems at times when I am tuning the receive goes dead. It can happen when I am pressing the up or down keys or scanning with the W1MT firmware. The problem went away a few weeks ago, and I had been using a 12V regulated suppy at 12.0 Volts since. But on Sunday, I went to a picnic using a 2.3 Ah gel cell that was at 12.89 Volts. I had a 5 Ohm series resistor in-line for tuuning but may have forgotten to use it at some time. But the receiver started going deaf again at times. I never got the end fed wire to tune up so I packed it away.

Last night I hooked it up to the regulated supply. The receive was still intermittant. I reflashed the memory and it was still intermittant for a few minutes. It finally went back to normal after awhile. I did not transmit at all since then.

I wonder if less than perfect SWR can damage the firmware? Anyway this has been bugging me for a while. I tried resoldering all the joints and there was no change.

I am building a Fuch's tuner for 40, 20 and 15 meters using a 21 meter wire. When I finish it I will do more transmit tests and see if the receive goes away again. See:

3070. ATS-3 rig durability, was: Dead Receive with 12v??

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-14 15:48:48 UTC
From: Vojtěch Bubník
Topic: 3066 Message: 3070

Hi Jim.

I actually had three problems with ATS-3a during its long life. And I have to admit I was not always gentle to it.

1) Burned finals. I am not sure whether it was caused by my tinkering with firmware or by high SWR. Anyway, -B shall be better with its final current probe.

2) One via connection was intermittent. It was a connection powering 5V stabilizer, so it was easy to trace. I soldered a wire powering the touch keyer on the stabilizer tab, maybe it put additional strain on the via.

3) One debouncing capacitor went dead. The chip SMD capacitors are quite sensitive to mechanical strain. The mechanical strain on the capacitor may be also caused by high temperature gradient during soldering. It is not visible that the capacitor is cracked.

I am a bit worried that problems 2) and 3) are caused by twisting of the thin circuit board. I would rather have the amateur construction on a standard 2mm thick PCB to make it more robust.

Vojtech,
How could you tell that a debouncing capacitor went dead? What was the rig doing?

I have touch keyer chip (QT113) outputs connected to key input and up/down tuning buttons. The chip has a heart beat feature, it superposes short zero pulses on the steady high level signal. The heart beat pulses were filtered out reliably for a long time by on board debouncing capacitors.

I found out, because I have the touch electrodes connected to up/down tuning. With the hartbeat signal the tuning is extremely fast. When I added another capacitor in parallel, the hartbeat diappeard.

I should also note that the rig is stock except for one mod, I added the 22K SMD resistor across C58 on the bottom of the board for the 'E' problem when cycling the power too fast. I also installed the capacitor for the LO output for the QSBA. It is tied to U7 Pin 20 (IOUTB), however this output was not connected to anything external at this point.

My question is: Why are people putting more than 12V into this rig
when it is my understanding that 12V is the maximum that it can
handle?

Is the 12V limit only a suggestion? Is it to avoid tripping the current
limit circuit during tune-up? Or to avoid toasting the finals?

While I find having problems with my rig to be stressful, in truth it
is probably the best way for me to get into understanding the circuit
and learning how the rig works.

Jim, its my understanding that you checked the voltages when the
receiver was 'dead'? And if that is the case, what was the voltage
on U6 pin 28?

Stephen:

U6 pin 28 is 3.47v, close enough to 3.5v. I don't think I ever ran with 12v before as I was using the QBSA to save the batteries. The QBSA tops out at around 10.7v or so. It was just my plan to use the 12v battery pack in the field.

Also I may have jumped the gun saying receive works running off the QBSA. It turns out I can hear white noise in the headphones, but on 40m I could not hear an S9 signal I was monitoring on the big rig. I did hear a weak signal on 20M on the 3B, but at a much lower level than on the big rig. Recheck the band modules? The TX seems to be OK putting out around 4w. I know 20M had worked before as I had a contest QSO into Iowa some time ago.

Oh well, it looks like the best thing to do is unsolder the connectors and remove the rig from the enclosure for debugging, sigh.

--- In AT_Sprint@yahoogroups.com, Stephen Wandling <swandling@...>
wrote:

Stephen,

1) Steve Weber suggests no more than 12.0V power input. Most of us
trust his experience with the various ATS rigs.

2) Others have blown finals, usually when running more than 10V.

3) When I run my ATS rigs at 12V and 5W into a good 50 ohm load, key
down for a minute or so, the finals and driver get warm. On the
higher frequencies the output sags a few percent, a sign than either
the finals are increasing their Rds, or the driver is heating up, or
both.

4) I'm uncomfortable when I see that power sag. It doesn't inspire
confidence. It certainly warns that raising the voltage higher is a
bad idea; likewise, running the rig into a mismatch is unwise, since
that can sometimes cause the PA supply current to rise higher than
when running with a 50 ohm load.

5) The peak swing on the PA mosfets is large, even with a perfect
match and supply voltage less tha 12.0V. Pushing this higher makes
no sense.

6) The rig is a nice compromise between light weight, low supply
requirements, high efficiency, and reasonable output. Enjoy!

Hi All,
My intent was not to encourage anyone to use more than 12.0 Volts into their rigs.

At say .7 Amps on tuneup the 5 Ohm resistor I use would drop the Voltage about 3.5 Volts to about (12.8V minus 3.5 V = 9.3 Volts). This is done in an effort to reduce problem of transmitting with a high SWR at full voltage while attempting to tune the rig.

For operating I have two sets of .33 Ohm resistors. At say .75 Amps operating at 1:1 SWR these would drop a supply about .5 Volt. This is meant to limit the voltage coming from a fully charged gel cell to around 12 Volts. The 2.3 AH gel cell I use is affordable ($16). I would rather have an 11.1 Volt lithium pack but for now I need to use the resistors.

Actually I have been using all three resistors during tune up. This should drop the supply voltage about 4 Volts.

I experience about a 10 hz drift over 15 minutes from cold (67 deg F) start on 40 meters. My second psk qso was plagued with the adjusting the down button problem; my conclusion was that the severe portion of the problem was on the other end.

As rough indicator, one can use the Pocketdigi software to jump to CHU or WWV, start up digipan and click on the signal and then note any frequency change over a time period.

Stephen Wandling <swandling@...> wrote: I reported here that on my first QSO with the ATS3-B on 80M, each time
the other guy came back, I had to hit the down button to raise the tone to a readable frequency. He was using separate boat anchors and might have been following me down, I don't know for sure, but we had a pretty long QSO.

Tonight was my second contact, on 40M. But, tonight the other guy made a long transmission and I had to hit the down button many times, (I kind of lost count) to keep the received tone the same. It just kept dropping every 10 or 15 seconds, But, this time, I used RIT, as I imagine I should have on the first contact. When he signed to me, I made a short transmission and then sent it back to dead air. He was gone. When I finally found him (up a couple of Khz), he was sending 73 and SK. I gave him a call but no response.

Something is obviously not right with the rig. I was on a 9V battery and the rig showed a voltage of 8V on startup, and about 7.7V when I lost him, so it shouldn't be a voltage problem. It's almost as if on the 80M contact the rig acted as though it was in RIT mode and tonight in RIT mod it acted like it was in 'regular' mode. (But I would have to contact the 80M guy to see if he noticed my frequency shifting or not.)

Definitely a mystery. I can't think of more to add right now, but if anyone has a question or an idea, I'm all ears.

72,
Stephen

To all the guys getting a "dead" receiver:

Which firmware are you using? (Trying to determine if it is common to both Steve's and mine)

At time of incident: What is the voltage at pin7/U6 (3rd programming pin from the side of board)

What is the voltage at junction of R45/R46?

Thanks,
Mike

Jim,

The reason I asked is that my first thought was that the Mute process was getting triggered. If your receiver seemed 'dead' and you have about 3.5v on U6 pin 28 then I guess its not the Mute. My next guess is that it involves the AGC circuit. Your reduced sensitivity seems to be consistent with an AGC problem, but it could be anything in the RF front end of the receiver. Maybe others can give you advice on how to proceed.

From the rest of your post, I am confused on your definition of a 'dead' receiver. If you start over with Steve's "

Need to raise a little cash to buy the new Portable Field Radio from qrpkits.com, so my ATS3 is for sale. The kit was started by someone else and I had to replace the DDS chip, so the soldering doesn't look as neat as it could be, but it works fine. The Altoids tin was done very quickly and doesn't look that great, I'll include a new tin (Hershey's Cacao Reserve) if you want to repackage it. It hears a 1 uV signal on all bands from my Norcal S9 Signal generator. Power with a 12V gel cell:
80M 5W 680mA
40M 5W 670mA
30M 4.5W 660mA
20M 4.5W 700mA
Photos here:
http://ph.groups.yahoo.com/group/AT_Sprint/photos/browse/f2f5
I think $160 is a fair price. Paypal preferred, but a postal money order is ok. I'll take a check if the shipping address matches your qrz.com address. Price includes shipping by USPS Priority Mail in the U.S. If I forgot anything, feel free to ask.
73,
Rob

3085. Straight Key and DFE

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-16 22:58:39 UTC
From: Stephen Wandling
Topic: 3085 Message: 3085

I'm clear that DFE is not currently available when using the SK. My question is Why? From my simplistic perspective, a SK can send numbers just as well as a paddle. On deeper reflection (2 seconds later :-)) I suspect that reading whether the dot or dash input is triggered is easier than discerning a dot from a dash.

Ok, I've probably answered my first question now on to the second one. [Or as Edward de Bono says "That's the first right answer".]

Why can't we hot switch from paddles to SK and back? Maybe have to hold a button when removing/inserting?

DFE is such a sweet feature to have on a button tuned rig. But, I hang around a bit with the SKCC (Straight Key Century Club) gang and its pretty labourious QSYing from 7030 to 7058 with the buttons. (I keep meaning to time myself while I "count seconds" so I can 'jump' to a new frequency without stopping and checking where I am 6 times.) I hope this doesn't mean will have to learn . . . . patience! :-P

This question must have come up before, but I haven't found any discussion on it.

Did Vojtech ever get "Fast Up" running? It isn't implemented on my rig, so there must have been some reason it can't happen?

These are the rantings of a crazed mind on a smokin' hot day in the Deadman Creek valley.

You're right, it's easier to read the dit or dah port rather than try to count lengths of dit's and dah's from a single input. Hence, DFE is only implemented for paddle mode.

It would, however, also be easy enough to add another menu option that would toggle from paddle to SK mode. Probably it hasn't been done before because it hasn't been something that Steve wanted nor I needed. Plus the pre 3b rigs had only 4k of program space so features were limited. The 3b uses an 8k ram mpu and is not being taxed yet. Contact me directly if you would want this and I'll try to help.

Steve's code is a reflection of what he wants in the rig and my firmware is a reflection of what I want in a rig. :) It appears that there is a unused port on the MPU and that brings up some interesting possibilities if one were inclined to make a hardware mod or two. Maybe even paddles and SK in the same package. Hmmmmm.

Right now I am working on improving the "iambicness" of the keying. Mode B in particular for high speed (40+) users. If anyone is a high speed Mode B keyer and can help me test let me know. Mode A folks as well. Does anyone use Ultimatic?

I am also thinking about adding a mode that will simply generate random sequences of characters (audio only, not transmitted).

Hope this wasn't too long a read.

To: AT_Sprint@yahoogroups.comFrom: w1mt@...: Fri, 16 May 2008 20:05:08 -0700Subject: Re: [AT_Sprint] Straight Key and DFE and other musings

You're right, it's easier to read the dit or dah portrather than try to count lengths of dit's and dah'sfrom a single input. Hence, DFE is only implementedfor paddle mode.It would, however, also be easy enough to add anothermenu option that would toggle from paddle to SK mode.Probably it hasn't been done before because it hasn'tbeen something that Steve wanted nor I needed. Plusthe pre 3b rigs had only 4k of program space sofeatures were limited. The 3b uses an 8k ram mpu andis not being taxed yet. Contact me directly if youwould want this and I'll try to help.Steve's code is a reflection of what he wants in therig and my firmware is a reflection of what I want ina rig. :) It appears that there is a unused port onthe MPU and that brings up some interestingpossibilities if one were inclined to make a hardwaremod or two. Maybe even paddles and SK in the samepackage. Hmmmmm.Right now I am working on improving the "iambicness"of the keying. Mode B in particular for high speed(40+) users. If anyone is a high speed Mode B keyerand can help me test let me know. Mode A folks aswell. Does anyone use Ultimatic?I am also thinking about adding a mode that willsimply generate random sequences of characters (audioonly, not transmitted). Hope this wasn't too long a read.-mike/w1mt--- Stephen Wandling <swandling@...> wrote:> Why can't we hot switch from paddles to SK and back?> Maybe have to > hold a button when removing/inserting?

This Sunday night is the night for May's Run For The Bacon.

If you're returning from Dayton; I hope you'll still have enough energy to join us!

As always, the details for this funfilled 2 hour QRP Sprint can be found at:

http://www.gentzow.com/fpqrp/fpqrprun.php

No. I had my ATS-3a flash memory full to the last bit. No space for extensions.
I received Steve's ATS-3b prototype, but did not have time to tinker with it yet.
Plenty of ideas, but so little time.

Reminder from: AT_Sprint Yahoo! Group
http://groups.yahoo.com/group/AT_Sprint/cal

Run for the Bacon
Sunday May 18, 2008
6:00 pm - 8:00 pm
(This event repeats every month on the third Sunday.)
Location: Your shack or anywhere

Notes:
This Sunday evening, the Flying Pigs Amateur Radio Club International will be holding its monthly Run For The Bacon. This is a friendly, two hour QRP CW Sprint, which is open to ALL radio amateurs, will last from 9:00 - 11:00PM EDT (0200-0400 UTC Monday).

You may work stations once per band on 160, 80, 40, 20, 15 or 10 Meters. Suggested starting frequencies are 1.812, 3.562, 7.044, 14.062, 21.062, and 28.062 MHz.

The exchange is RST, S/P/C (State, Province, Country) and Flying Pigs membership number. If you're not a member of the Flying Pigs, and would like to be; then please cli

3092. Hendricks "Portable Field Radio" -- Nice!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-19 13:26:05 UTC
From: Steve
Topic: 3092 Message: 3092

For KD1JV fans... this is a real nice, totally self contained field radio kit introduced this past weekend at the Dayton Hamvention.

http://www.qrpkits.com/pfr3.html

A KD1JV transceiver, integrated and packaged by Doug with an internal tuner, SWR indicator, display, battery power, case, and (optional) paddles. A single circuit board blends SMT and thru-hole parts. However, all the SMT parts are pre-mounted! (My guess from looking at the sample? About 15% SMT parts.)

This band-switched, 20/30/40M 5W rig is truly self contained. All you need to add is an antenna of your choosing!

Now... to find the time to put mine together!
73,
Steve

3093. Altoids Longwire Tuner Diodes (Tayloe SWR indicator question)

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-19 14:06:02 UTC
From: kc7fys
Topic: 3093 Message: 3093

Howdy,
I put together my own copy of the Altoids Longwire Tuner <http://www.qrpkits.com/altoidslongwire.html> , and think I may have done better than in past non-kit outings, but I may not have selected appropriate diodes. What type of LED is appropriate for this SWR indicator? The pdf for the SLT kit calls for a "Super Brite Clear LED (RED)." What specs should I be asking for for this LED? When I apply about 2.5watts RF to the input of this particular tuner, I get about 9.4V where the LED is wired in, but the LED doesn't light.
Also, the other diode in this Tayloe SWR bridge is a SD101C (in the kit version) and an IS953 that I installed (probably not the right diode, despite 'looking' the same [audience laughs]).
What should I be looking for for this application for these two <http://www.flickr.com/photos/jonathancharles/2504805817/> diodes?
Thanks,
Jonathan KC7FYS

Ha ha, those jumpers are from Yodobashi Camera (I'm in JA) in the DOS/V computer section. That knob for the cap came with the cap for a buck in Akihabara.
I'll have to try a few diodes myself. The schottky, though, there's no substitute for that.

Jonathan,

When I built my homebrew BLT, I had some LEDs lying around;
some had been removed from other gear. I went on Wikipedia to
see which side was the cathode. Following the information I got
there, I installed the LED and it did not light. Of course, it was in
backwards. So, that's going to be my guess.

HI Jonathan,
The flat side of the led should be closest to ground.

I am guessing that any silcon or germanium diode should work if the power is around one watt. But you may need more power. The voltage drop of a silicon diode is about .6 V while the voltage drop of a Schotkey diode is a lot less allowing lower voltages to pass (I think)

The band on the diode should point away from the toroid and towards the resistor.

I am guessing also that if the led and diode polarity is not in the same direction there will be no current flow.

Good luck. Isn't this fun!

Hi Hank.

I built one portable Z-match with this kind of LED SWR meter and it worked perfectly. One tunes to the minimum of the light emitted by the LED diode and the minimum is very sharp. So you do not know the SWR exactly, but you could be pretty sure, that you found the best minimum.

NAQCC Sprint Wednesday night!
This coming Wednesday evening will be the monthly NAQCC Sprint for May, 2008.

I will refer you to the proper URL:

http://www.arm-tek.net/~yoel/sprint200805.html

There you will find all the details as to time, frequencies, this month's Special Award, which will be awarded to the one working the most different call areas in the USA.

This is a monthly event that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate; but you must use QRP power levels to compete for awards.

Come join us and have a real good time!

73 de Dave VA3RJ

If it is for a varicap app, just use a 1N4007. It works really good.
Don't use others of the family 1N400x ! The 1N4007 has a pin structure.

regards -
Henry

Well now, I, understand that the color presented is a bit on the bright side... but then, I don't have to see the radio much, but I do need to listen to it. I also know that there is a very happy porcupine, or mountain cat, maybe a deer, or a rabbit... a wolf or maybe the whole bunch of them... all gathered around a litte radio...that found its way to the top of a rock... way up the mountain.... in the Bridger-Teton Wilderness, and decided to stay... it hide out nicely... being about the same color.. Now, I am betting that they never got on the air with it... and if they did, they didn't use my call.... but just listen... for a moment... to the talk on the wide side... wow... what a Qso that would be.
Anyway, I figure that the little Yellow Wonder... will not try to hide out... it will be a nice addition to my saddle bag... or bedroll. Strapped on the back of the saddle, it will be a nifty addition.

I'm of the opinion that the markings on LEDs is not yet pure science. Wikipedia says: "While the only definitive way to determine the polarity of the LED is to examine its datasheet, these methods are usually reliable:" They then go on to mention that the cathode is the shortest lead or the flat side is the cathode.

Regarding your circuit, the schematic shows the cathode of the LED going to ground, so if that's the way you had it then you had it right. As someone else here has said, the polarity of the LED and the diode have to be the same for the circuit to work. So, if your circuit works now, I suspect that if you (don't do this, I'm just making a point) reverse both the LED and the diode, it would still work exactly the same.

Some are confused by the arrow in a diode or LED, probably thinking that is the direction of current flow. Not too many years ago, we did think that 'current' flowed from the positive (surplus) side of a battery, through the circuit and then to the negative (deficiency) side of the battery. We now know that electrons flow from negative to positive; against the arrow.

While we're almost on the topic of what we think we know or what we know but don't talk about, I'd like to mention magnets. If you hang a science course bar magnet on a thread from its middle the end marked "N" will point north. Everyone knows that. But, if the north pole of a magnet points to the pole of another magnet, then they must be unlike poles. So, either all of the bar magnets are mis-marked or the poles of the planet earth are not named appropriately. I find it strange that this doesn't seem to come up in school or in the industry. I brought it up in 1961, regarding the polarity of a traveling wave tube focus magnet when I worked at Varian Associates and was laid off shortly thereafter. I gather I offended some engineers, who simply couldn't answer my question.

Thanks for bringing up this circuit. I had recently tacked together a tuner for an End Fed Half Wave antenna, from a circuit that Steve (The Goatman), N0TU pointed us towards: http://www.aa5tb.com/coupler.html Steve Yates, AA5TB, has done quite a bit of research into the subject; some of which I grasp and some I don't.

The AA5TB tuners are for resonant half wave antennas. I gather that the ALT/SLT tuners by Steve Weber are not for resonant antennas, but for a 51' wire and counterpoise. I find the idea of one tuner and one wire antenna to be very attractive for portable work. But, the ALT/SLT seems to fly in the face of what I am hearing from AA5TB.

Any antenna/tuner gurus out there that can sort this out?

--- In AT_Sprint@yahoogroups.com, Stephen Wandling <swandling@...>
wrote:

Stephen and others,

I wrote a bunch of words here several month ago about my version of the ALT/SLT. The key point is to use a quality DIP switch to switch the inductor set. This proved to be a great idea in the field. Jumpers are a hassle, and switches are bulky. I use a Grayhill 8-bit DIP switch, and it works just fine. If you build this type of tuner, please consider this space-saving, convenient trick.

To find my earlier postings, search for Grayhill or DIP on this site.

My DLT tunes many combinations of end-fed wires and counterpoises on various bands. This January I used an 82-foot wire on 20, 30, 40, and 80M with the little tuner, a counterpoise of about 25 feet, and the ATS-B. I worked VP9 and KH6 with this wire, 20 feet up, on 40M, from a ski hut at 11,700 feet near Leadville, CO. I carried all the gear, about 3 lb total, up three miles in a backpack, wearing snowshoes, and somehow got the wire up while wallowing in deep snowdrifts. Does the tuner work? Awesomely!!!

Field tests and Eznec models reveal that short counterpoises, like 16 feet on 40M, work quite well with antenna lengths near 1/2 wave. A quarter wave counterpoise may be undesirable, as it tries to lower the feed impedance. You want a high impedance feed with an end-fed half wave, so you can get the current lobe up high, away from the ground.

The only problem with the high-Z feed at QRP levels is that it's subject to capacitance effects. You need to sit still once you get a good match. It's a minor hassle - not having to carry a feedline is a plus.

There is a photo of the tuner in the PHOTOS section here. My version not only has the DIP switch, but also additional jumpers allowing for several different configurations of the various components. I use two polyvaricons, which helps get matches faster.

If the LED goes out the match is very nice. I verified this with both BLT's and the DLT with an MFJ-259B. The Dan Tayloe circuit with the BLT is excellent. Doug Hendricks sells these null indicators as a sub-kit.

To get the polarity of the diode and LED correct, you only need to match the LED to the diode. The schottky diode can go either way.

If in doubt, test with a current-limited power supply, or a 9V battery with a 470-ohm resistor in series. For testing small LED's, limit current to 25 mA max. 10 to 20 mA is nice.

Most LED's have a bar-shaped "platform" part inside that holds the die. This looks like a minus sign and is usually negative. If in doubt, test the led and mark a lead with a marking pen to avoid reversal.

Use a schottky detector diode if you want good performance at QRP levels. A germanium diode also works well. A silicon diode will reduce the sensitivity, and you may not be able to get a nice bright led and good null with 1W or less unless you use the low-threshold diodes.

I think if you build an ALT with jumpers, you will go nuts using it, unless you use it with the same antenna and band setup all the time.

T match tuners could be built with DIP switches and toroids as well. I don't know whether the polyvaricons will handle the voltages in a T-match at 5W.

Yes, I was mindful of your DIP setup that you were building back some months. The time and money invested will allow me to build both. At my level, this is primarily educational. Every time I mess something up or build it right, I learn something. I've been QRPing for just a couple years, so I've got lots of room to learn.
I'll check out your photos--and may ask you further clarifying questions, Carey,
Thanks,
Jonathan

3111. KX0R DIP ALT

Yahoo group: AT_Sprint (2002 — 2008)

From: kc7fys
Topic: 3103 Message: 3111

A couple comments on your design, which I might as well copy sometime down the line here.

First of all--sassy knobs! Did you fabricate them yourself? They serve the dual purpose of obvious functionality and allowing the PVCons to be seen.

I notice you wound your (is it called the 'detector'?) FT37-61 with interlaced secondary windings the first time--and separated them by quite a bit the second iteration--why's that?

So you don't have to chew your cabbage twice, I'll check back in the old posts--but what were the inductances of your seven toroids there?

I assume you left the SIP pins because they were a hassle to desolder--is that the case?

What I like about this unit, and especially if a male RCA plug terminates that input line, is that it really shrinks down my go-bag if I decide to leave all the partly-needed stuff behind. It eliminates a lot of connectors that I currently carry around. (I'm gonna one of these days snip all the BNCs out of my setup and go with RCAs finally.)

I'll do a search and read what I only half paid attention to the first time.
Regards,
Jonathan
PS. Your filter mods were such a hit with my setup that I'm eager to add the KX0R DIP ALT to my grab-and-go kit.

Steve et al,

You don't need much time to build it. For a bit of fun it took me just a little over 6 hours to build (30 minutes was winding the torroids) and I built mine whilst at FDIM, I collected the kit from Doug on the Thursday night and showed him the built kit Saturday night. His stall was across the way from the homebrew contest, and I put most of it together during the buildathon, Friday PM. I had boobed and put 22K values in R6 & R7 and not the 330K needed, silly mistake soon fixed, too much Sam Adams from the FDIM bar and not double checking values! The 4.7pF capacitor supplied in the kits at FDIM is a green 5pF capacitor not the 4.7pF NPO disk as listed on BOM. I discussed with Doug and team, they even had put in an extra cap 0.1uF and an additional 4K7 resistor so the kitting was fine.

The LED display you test in step 1 tests if you have a problem with the decimal point and the lowest of the 7 segment displays look at the 2 driver resistors on the right of the LED just below the 6 in a row. Mine were not soldered though enough as the 1/4 watt resistors body is just too long for the holes so I had to lift one end and resolder and make sure the solder came through hole. Any problem with other segments, trace which resistor in the bank is the driver and check the solder joint. The same segment in all four digits wil be effected.

Operationally I have noted that when you change band you have to change BOTH switches to switch in and out the 20m, 30m or 40m LPF. I suspect you will have to watch that.

One change I might suggest once I find the correct threads is to swap in thumb screws that will fit the case instead of the 4 tiny recessed screws as it is going to be a right pain fiddling with those screws

to change batteries in the field. Seem to be same as those you'll find on MFJ kit.

The yellow colour on mine top and bottom were slightly different but you have to look very closely to notice.

I will use a small case for mine, to include wire antenna and spare battery as the knobs and controls are all external and it might not fair too well knocked about in a ruck sack.

Vojtech,

That's good news to hear that "Fast Up" is still possible. For the paddle users, it may not be much of a bonus, but I spend lots of time using my straight key, and I sure would value it.

Thank you for all of your contributions to Steve's ATS rigs.

I would also liked to have seen a different fast tune up or tune down function. I would like to be able to hold then release the Tune Up or Tune Down button and have the scan continue until either button is hit again, and have it loop around when reaching the band edge. This would be great for looking for activity.

I think much of the difficulty that I have with the keying in the ATS-3B (and I imagine it's the same in the others) is that the algorithm just isn't right. In both Steve's firmware and nit Mike's, which implements the same algorithm with code that's more compact, paddle inputs are completely ignored during the inter-element delay. This leaves a very tiny window of opportunity during the last 2/3 of a dit for the rig to see the dash paddle and queue the dah. There is a bit more of a window to queue a dit simply because the dah is three times as long as a dit.

If the firmware was modified to observe paddle inputs during the inter-element space, I believe the ATS's mode A would be equivalent to what most people term Iambic Mode B, where a momentary tap on the opposite paddle any time just after the beginning of the element to the end of the following inter-element space would queue the opposite element. I've modified mine to do this and keying is *much* easier.

As for the ATS's mode B, to me, this mode seems really bizarre. As implemented, it appears to queue a di-dah or dah-dit sequence if both paddles are observed to be closed at the trailing edge of an element. It seems to leave almost no margin for error; I can't see how one could consistently avoid getting an 'R' when intending to iambically send an 'A' unless the keying speed was set very, very low. One would probably have to key the 'A' non-iambically to make sure that only one paddle was down at a time.

To get what I believe is commonly referred to as Iambic mode A, which doesn't send the opposite element unless the opposite paddle is still closed when it comes time to send the next element, the firmware could be changed to simply toss the queued element unless it's paddle is still down. I have not tried this change since I intend to use Iambic mode B. Keying in a manner that is compatible with Iambic mode A will produce the same results with Iambic mode B as long as there are no unintentional momentary opposite-paddle closures that would be ignored with an Iambic-mode-A keyer.

If anyone knows of a (non-ATS) reference that describes a keyer that defines modes A and B the same as the ATS, please let me know. I would like to study it.

--- In AT_Sprint@yahoogroups.com, "Dave" <dmertz@...> wrote:

Dave,

Thanks for this post. I've wondered for some time why the ATS-3A and B keying seems harder to use than my CMOS-4, TICK, and K12 keyers. Normally I use Mode A, and I find it a bit harder to use the iambic characters with the ATS rigs. The rigs seem to make errors, or I seem to make errors, with the result that I often just send without the iambic motions. It ends up being more like single lever style.

I don't know enough about the code to comment, but there is a difference between the ATS mode A and the mode A on other keyers I have here. I'm not a sharp enough sender to put my finger on what the problem is. Usually I use my ATS rigs with Palm paddles, which are not the most precise or solid, so I've been blaming them for my errors. I think that imprecise timing in the code multiplies the problems caused by the paddles and the operator.

I hope some other ops will comment here on what they feel.

Perhaps there are enough of us Mode A people that someone will revise the code...wonder if it's the same on the new yellow box rig?

Mike attached his latest ATS-3B firmware that includes mods to the keying algorithm intended to produce the commonly expected operation for Iambic mode A and B. He included me directly on the distribution so I have the code and have made a few suggestions to Mike directly.

Once it's finalized, I think it will work nicely, but of course only if it's loaded into your 3B. Putting the same algorithm into Steve's code for the 3B would be a bit more work because of the way that support for paddle reversing was implemented. Mike's code does not include the digi-modes since he essentially added 3B support to his version of 3/3A code, but it gives you other very nice CW-related features.

Carey,

It was code. I forgot and sent it to the list. I will send it directly. (Anyone that wants to test it let me know).

Don't be afraid to reload firmware. It's easy and the instructions are on my website. You only need a few resistors and some cabling and a computer with a parallel port.

Make the cable according to:
< http://groups.yahoo.com/group/AT_Sprint/message/1869
>
< http://groups.yahoo.com/group/AT_Sprint/message/1884

It really is easy.

I believe I have most of my receiver problems corrected. After I had originally peaked the receiver trimmers I went and did the kx0r mods to get a consistent power output on all bands. I did not think to re-do the receiver alignment at the time.

So I re-peaked the rx using Spectrogram and my N0SS broadband hf noise generator. I can now hear some signals though weak as the bands are not in great shape.

I still have a problem with 80m, I only get one peak on trimmer CT2 and no peaks on CT3. The peak noise level in Spectrogram is 30db lower than the other bands. I did not make any kx0r mods on this module as I was able to get 4w out with the QBSA's max 10.7v DC output voltage, my goal for all bands.

Has anyone else had this problem on their 80m module? Looks like I will have to try experimenting with component values to get good double peaks on the trimmers.

The recv front end is a double tuned tank circuit.

You may need to add C to the trimmers via C5F and C7F.
I made C5F 100pF and C7F 68pF.

--- In AT_Sprint@yahoogroups.com, Michael Harnage <w1mt@...> wrote:

Jim,

Mike is right. The default values for the receive filter on 80M are set too high for tuning at 3.560 Mhz. Mike added capacitance. I went beyond that and changed the inductor from the molded 18 uH unit supplied to a toroid, measuring 22 uH. I also increased C5F and C7F.

Please see my details on the filter mods paper. I ended up with real nice receiver performance on 80M.

I started out with really weak sensitivity on 80M. I was maybe 40 db from where I should have been. After going down a lot of blind alleys, I found a tiny solder bridge across one of the pads for one of the receive filter inductors. I'd suggest you do a close inspection, with as bright a light as you can find, and serious magnification. Look at everything in the receive signal path. Look for cracked capacitors, solder bridges, and especially magnet wire where the enamel isn't stripped and soldered nicely. Follow the signal on the schematic, step-by-step, while you inspect each point on the filter board.

If you don't find a visual problem, you can inject a known signal into the receiver and trace it with a scope. Try it on 40M, since that band works OK; write down the levels as you follow the signal through. Then go to 80M and see where the signal drops or doesn't pass. You should not put too large a signal into your receiver, but you can inject enough to see something on an average scope. I have to admit I don't know what the damage level is for this receiver. Minus 20 dbm should be safe; 0 dbm might be OK; more is probably unwise. The scope probe will detune the circuits somewhat, but by comparing 40M and 80M you should be able to find a major problem in the module. 30 db down is a short, an open, or something else bad wrong.

Be patient enough to get the double peak so you can adjust for max. If there's a short or some other bad problem, you may not be able to find resonance until the fault is corrected. It's probably best to find the fault and then do the final tuning.

It's a good receiver. On 80M it will still hear many signals when the band's active, even with a shorted front end. Signals are strong on 80M. I had a nice QSO with someone on 80M before I found that solder bridge.

Good luck -

Thanks for the feedback guys. I moved the 68pf capacitor in C5 over to C7 and placed a 100pf at C7. I now have double peaks on CT2 at a significantly higher level than before, but still less than the other bands.

However, I still get no peaks on CT3. I unsoldered and switched the trimmer caps at CT2 and CT3 just in case I had a bad one. But the result was the same, CT3 won't peak. Does anyone know the value of these trimmer caps??

I am now considering doing Carey's mod on this module. I don't have the capacitor values handy. And though I have the core and #30 wire, I'm not sure I want to wind another toroid, especially one with 75 turns! I think I will pick up a 22uH molded inductor instead. So I am on hold until Tuesday when I can get parts.

Thanks again for the help guys!

3129. New W1MT firmware posted

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-26 02:28:58 UTC
From: w1mt
Topic: 3129 Message: 3129

For all you guys who have been checking out my firmware, I have just posted a couple of versions for the 3B on my website. They include a fix that I don't know how I missed originally but you will want it if you have a previous version 4 or version 5 of my firmware. The ones posted fix the reset code (which I had skipped over rather than do the 22k resistor mod) and a fix to the scanmode that I somehow missed before. Sorry for any inconvenience this may have caused. I won't be using version 4 or 5 again, I promise. Next will be version 6. Still looking for some users of the old Accukeyer to give some comments on the keying in version 5.

--- In AT_Sprint@yahoogroups.com, "Jim Fraser" <jimf53@...> wrote:

Jim,

Please verify that the connections on LF3 are correct. The leads from from the 6-turn link must go to P2 and ground. Otherwise the circuit won't tune.

Verify that the leads from the big winding go to ground and to CT3, C5F, and C9F.

If you have the double peak on CT2, you may not have to do anything to LF4. There's no need to wind another toroid, and maybe no need to change from 18uH to 22uH.

There's some fundamental problem if CT3 won't tune AND the sensitivity is low. It's a short, miswire, open, bad part, etc. 99% of these problems are solder problems, like shorts or no connection. Look really hard at those little magnet wires coming out of LF3. The solder connections should be nice, with solder visibly bonded to copper, and no tiny bridges on any of the pads. Trace and check every lead from LF3.

A meter won't help, since every connection of LF3 should read nearly zero ohms to ground.

Use a bright light, good magnification, and you'll find it. It's a 3D puzzle, but not a complicated circuit. When you get it fixed, 80M will be hot, with plenty of band noise, even if LF3 is not tuned quite right.

Success! After examining the solder connections it did appear that maybe one or two points on LF3 may not be making good contact. The only way to be sure was to pull the transformer. I removed a slight bit more enamel on a couple ends that could be suspect and re-installed. The receiver now double peaks with both CT2 and CT3 and the output level matches the other bands.

Looks like I can finally call my 3B complete. All I have left to do is wire in the touch keyer module. I'm looking forward to Field Day when I can give this thing a good test.

Now on to other projects I have lined up, including a partially-completed SoftRock RXTX 40/30, time to wind some more toroids!

Thanks Mike and Carey for all your help.

Jim,

I too had low receive on 80M and no peak on CT3. It turned out
that I had switched two primary/secondary wires on LF3. I too
cried Success when I fixed that.

But, now I have learned that maybe I was only part way home. I
will be changing the two capacitors that Michael recommend. If
all goes well, I may apply for membership in the CT2/CT3
'double peak' club! :-)

My first portable ops with the Bee this weekend. The contest at
least let me know the bands were open. I was set up to work
80M-20M on an end fed wire, through the BLT, and I made Qs
on every band. It all worked great once I got the counterpoise
stuff sorted out. Thanks for your advice Carey.

72,
Stephen

Jim,

Nice to read your good news! I thought LF3 was the trickiest component in the kit. Several of us have had issues with it. The small magnet wire ought to be easy to solder, but it's not always so.

I recently found out that liquid solder flux helps when tinning or soldering magnet wire. The basic steps are: scratch the wire with an Xacto knife where you want to tin it, apply a drop of liquid flux, and tin the wire with your soldering iron and rosin core solder. Of course a solder pot helps, but most of us don't have one.

On some late winter nights, 80M is the best band on the ATS-3 rigs, since we're near solar minimum. 40M goes long, and many ops pull the switch, but there's still good activity on 80M. Because solar activity is so low, losses on 80M are lower at night than in more active years, so QRP works well. A big antenna helps, but you can have real QSO's, even with a 65 foot dipole up 35 feet, fed with ladder line and a tuner, on 80M. I would not have said this several years ago.

--- In AT_Sprint@yahoogroups.com, "w1mt" <w1mt@...> wrote:

Mike,

I looked at your website and downloaded a file called ats3b_m005.s43. I believe that this is version 5, and you have already updated it to 6, I think.

In order to learn how to update the firmware, I'm going to reveal my lack of knowledge and ask questions that may seem unnecessary to people who're familiar with firmware and programming. Believe it or not, I have some knowledge of what is happening, but there are gaps that I can't bridge without asking several questions.

I've actually loaded firmware on boards, using equipment built by others, and I've been trained that processors can be damaged if things aren't done correctly. Connections must be correct, levels correct, and steps done in the right order. I don't see much room for creativity in the process.

I think what is needed is a step-by-step set of instructions for the novice. Please assume that most of us have little experience, and list all the steps required. That way any reasonably motivated person could actually succeed, instead of getting frustrated or possibly disabling his radio.

I can see several steps and many big gaps:

1) Download the firmware from your website
2) Save it somewhere on my computer where it can be found again
3) Get a program from TI?
4) Install it? Are there questions to answer during installation? Is special knowledge required to do the install?
5) It's not the latest version?
6) Open this program and follow your instructions
7) Then I have a big gap - it appears I need to purchase or acquire some kind of device from TI - it costs $49? I saw someting about I compiler and I freaked out.
8) But, it appears there may be a less expensive alternative, but I can't tell what's best for me, with little experience
9) Yet others suggest it's easier than that - I just need to make some kind of simple interface with resistors in each parallel line
10) I understand I need a parallel port on my computer
11) My machine has a DB25 connector for my printer - is this the port I need? I have never in my life used the parallel port on a computer for anything but a printer.
12) I have no idea which leads go where

13) I know nothing about the conventions, the voltage levels, or which signals are on which lines
14) I would need a drawing or wiring list to know what goes where, since I understand that each line carries data for a specific bit
15) I would like to read through the entire process in detail before beginning, in order to judge whether I want to start at all
16) I suspect that many others feel exactly the same way, but are reluctant to admit how little they understand about this process.
17) This is not just a thing where you hook up a USB cable, click a couple of steps on a menu, and you're done. I can do that. I can load maps onto my GPS, download my digital photos, etc.
18) I think anyone who built an ATS3-B successfully can probably load your firmware perfectly, but we need training and instructions. Most of us are not programmers, engineers, or digital people. Many of us stretched ourselves a little to build, debug, and perfect our ATS rigs.
19) I'm amazed that anyone - Steve, you, or anyone - could write all that code, unless they were compensated in some large manner. It's awesome. This actually makes it harder for me to figure out how to get and use your code!
20) I think that if you would write something like 30 to 50 lines of instructions, or more, the number of users of your code might increase significantly.
21) It doens't seem logical to write this much code and not have it used by many possible "customers"
21) I have to be both ignorant and blunt here to get past where I'm stuck - I need a program to follow in order to succeed
22) There are a lot of steps required to actually do this process right, first time, no errors, and I don't know the steps.
23) Am I missing something fundamental here, like, do these instructions already exist? Has some already written this up?
24) Most of us naturally might want to be able to return to Steve's code, some day perhaps, but likewise we have no idea how to do that, if we don't know how to load your code. We're blocked. Stalled.
25) Just because some bright, experienced people already know how to do this, or are smart enough to figure it out, doesn't mean that the rest of us can jump the gaps and figure out what to do.
26) It's hard to write clear instructions for others to follow, particularly when those others are not at your level, or when they lack experience.
27) I hope you'll help us out, because you've created something really significant for the ATS radios, and you want people to share this.
28) We really need a cookbook recipe with every single step and definition. We really are that clueless.
29) Some of us are willing to learn.

Thanks

72

Carey,

Thanks for this. While firmware is still a bit down the line for
me I did take a look at Mike's site and I definitely found that there
seemed to be assumptions/presumptions as to my knowledge
which left me feeling lost. Something that's step by step as you
suggest written in everyday language is needed before I subject
my Bee to this process.

V5 is my latest. V6 will be the next one (not published yet.)

There is a step by step procedure at my website, it's at:

< http://w1mt.qrpradio.com/IAR_setup.txt >

Keep in mind that it was written when the ATS-3 came out so you will have to put MSP430F1232 vice MSP430F1121A but everything else is the same.

If you use the IAR suite that I have on my website you can follow it exactly. If you use the latest IAR suite from TI then you will have to change a few things. I still use the older IAR suite.

As far as messing up your rig, I have yet to see it happen. I don't think you can mess it up.

Hope this helps. Let me know if that procedure link above leaves any more questions...

3138. Cable for programming the ATS rigs

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-05-28 11:11:04 UTC
From: Michael Harnage
Topic: 3138 Message: 3138

This is originally from Steve. I have changed the
resistors according to Steve's subsequent testing.

All you need is a male DB-25 connector for the
parallel port, a 7 pin SIP pin to plug into the ATS
board, and 6, 220 ohm resistors.

We'll number the pins on the ATS board left to right
as 1 to 7, ground
being pin 1.

ATS pin >> resistor >> DB25 pin
1 none 18 to 25 (all grounds connected together)
2 220 16
3 220 1
4 220 4
5 220 3
6 220 2
7 220 ohm 12

The resistors do a voltage translation from the 4-5
volt output of the parallel port to the 3.5 volt
supply of the MPU. The resistor values aren't very
critical, a size up or down from those shown should
work okay.

3139. ATS3B

Hello Forum Members

I built my ATS3b, and i have same troubles:

1. When the rig is to pwr connected i hear only constant very high tone in the earphones.

2. From time to time when i connect pwr to the rig i get the high current indication, but ther is noc high current situation.

As info: if i press the key i have approx. 2.5watts output and the high tone is not any more present.

TKS how replay to.

Nice regards Rolf

Steve's recommendation for eliminating the "E" at power-up:
http://groups.yahoo.com/group/AT_Sprint/message/1585

> As info: if i press the key i have approx. 2.5watts output and the
> high tone is not any more present.

That suggests that the problem is in the receive circuit. Is the
2.5W signal on the correct frequency? Does the rig indicate the
frequency in Morse code and on the LED correctly? If you get a
good indication on the LED but not by Morse code, and the Tx output
is on the correct frequency, the problem is probably in the audio
section near U4 or U3b.

Dave, WA3OFF

Rolf,

- Were you successful in all of the "Check out and Calibration" steps on pages 23 and 24?

- Is the 'very high tone" referring to its frequency or its volume?

- Have you checked all of the voltages on page 27?
Do not despair, your Bee will "sing".

Hi;
I'd like to buy a QRP Base Station Accessory (QBSA) by Steven Weber,
KD1JV, in either kit form or assembled.
I can pay via PayPal, Check $US, Cheque $CDN, or other.
This is to complement my marvelous ATS-3B!
Let me know what you have.
Thanks,

Hi Jonathan,

I haven't yet tried transmitting with the jornada, but I have
with a thinkpad and a simple interface as listed in the manual.
Don't remember the exact specs on it. I hope to try out the
jornada for psk soon and will post my results when I have.

The same interface should work from the headphone audio jack
on the jornada since that is all I was using on the thinkpad.

73,
Bill, ni5x.

3158. ATSIII Wont Go to Straight Key Mode

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-03 02:13:00 UTC
From: c6alk
Topic: 3158 Message: 3158

Hi Steve:

I hate to bother the group with this, but I have tried everything that I know of to try and remedy this situation. I have acquired an ATSIII already built. It has worked just fine for several weeks, but recently developed a fault. When I insert a mono plug into the paddle jack, the keyer does not go into straight key mode as before. I went through each menu selection, and attempted to see if there were any undocumented menu selections that may have changed this mode selection, but no joy. I tried Iambic, mode A and mode B. The mono plug has worked perfectly before. I traced the circuit from the paddle jack up to the input pins on the microcontroller, with and without the mono plug inserted, and all looks OK. Somehow, I feel like I have something set wrong in firmware, but I have not a clue to this point. I am all out of ideas. Can someone give me a hint of where to go next?

The only time the port is tested to see if a straight key is attached is at boot up. The straight key needs to be plugged in when power is applied. You can't change it after boot up. Not sure if that is causing your issue?

You can test using a paddle, hold the dah paddle closed while applying power then after boot up use the dit as a straight key (you can release the dah after boot). This will tell you if its the rig or the plug of the straight key.

3162. Re: ATSIII Wont Go to Straight Key Mode

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-03 14:28:24 UTC
From: c6alk
Topic: 3158 Message: 3162

Hello Stephen and group:

Sorry, I should have mentioned the effects of plugging in the mono plug into the key jack. First of all, I made sure that the plug was indeed fully inserted into the paddle jack. I ensured that the plug sleeve was not connected to ground on the outside of the case.

The rig seems to transmit dashes continously as if I was using a paddle wth a stereo plug held to the dash side, from the built-in keyer. Removing the plug causes normal RX operation, keying ceases. There is actual keying of the transmitter, BTW, as normal RF is being seen.

Inserting a blank stereo plug causes no keying at all, exactly what is expected in that case.

For some reason, the microcontroller seems not to be detecting the mono plug. As I mentioned previously, the tip, ring and sleeve connections are correct at the microcontroller pins.

In other words, ground appears at the ring (dash) connection at pin 8 of U-10, and the tip (dot) connection at pin 9 is open. Shorting the dot connection to the ring (straight key keying) causes the dot connection to show ground, all as expected.

This continuity testing was all done with the PCB out of the Altoids case of course.

The weird keying problem ocurrs when the rig is in the Altoids case, but I have no way to check under the board when mounted, if some sort of short is ocurring when the PCB is monuted in the case.

I am beginning to suspect the case though. I will remove the pcb and Hot test it on the bench to see if the problem persists.

I doubt very seriously if this is the cause though. I sure would appreciate anyone's input, simple problem, but it's driving me nuts and prevented me from entering into the Spartan Sprint last night.

If you can please reply to me directly as well as to the group, as I get the group list in digest form, and it can take up to a day to get any replies from the group itself.

Brian K7RE

Hi Mike and Group:

Yep, having the plug inserted BEFORE boot-up did the trick! The straight key function now works properly. Too bad that I didn't think of this obvious solution before. It just never popped into my mind. I really appreciate the help. Hopefully, in the next edition of the manual for the next run of the ATS3B, the fact that the mono key plug must be inserted *BEFORE* power up will be mentioned. Makes perfect sense after the fact! HI!

Thanks again for all who helped poit tne way.

Just checked the current manual and it's already there:

From page 9:

External Straight key mode is automatically detected and enabled as the rig is powered up when a monaural
plug is in the paddle jack. The sleeve of the mono plug grounds the dash input, which enables straight key
mode. Straight key mode also allows use of an external keyer if one so desires.

Yes, it is very well stated in ATS3B manual, glad to see that, but not so clear in the ATS3 manual. At least it is documented now in this group for people who are as unobservant to the manual as myself! BTW, I take the rig out with me daily when I walk my dog for about 45 minutes. I have a small backpack setup with a Hustler mobile antenna. I drag a short counterpoise. Power is a simply 8 cell AA NIMH battery pack. I haven't yet tried to make any QSO's on these trips, just listen. I'm 63 years old with a bad back, so true backpack camping would be difficult. The rig is certainly a marvel of engineering, as well as enjoyable to use, and I am very impressed. Thanks again for all of the help.

Straight key mode is described on page 7 of my ATS3 (not A, not B)
manual on Page 7. At least on my version, rev B dated 12/4/2004. This
is the same way all of Steve's keyer rountines have worked for as long
as I can recall. Have fun.

NAQCC Sprint Tuesday night!
This coming Tuesday evening will be the monthly NAQCC Sprint for June, 2008.

I will refer you to the proper URL:

http://www.arm-tek.net/~yoel/sprint200806.html

There you will find all the details as to time, frequencies and also a special prize.

Since this is Field Day month, our special award goes to the one making the highest score while operating out of doors away from their regular QTH.

This is a monthly event that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate; but you must use QRP power levels to compete for awards.

Come join us and have a real good time!

73 de Dave VA3RJ
NAQCC #0004

3168. Low Audio?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-07 21:01:07 UTC
From: Jim Fraser
Topic: 3168 Message: 3168

I did some comparisons between my RockMite40 and ATS-3B and it seems that maybe the audio output on the 3B is much lower.

With no antenna attached, both the RM40 and 3B (40M module) have a low background hiss. After attaching the antenna the background noise on the 3B is the same, but the RM40 is significantly higher. The sidetone level on the 3B is fine.

When I replaced the antenna with my N0SS Noise Generator, the 3B had what I thought was a more normal background noise level. On the RM40 it was way too loud.

I do hear signals on the 3B, but they seem more robust on the RockMite. I am concerned that I may not hear the weaker signals with the 3B. Yes I have the trimmers peaked on the band modules. All other bands also seem to be low.

Does it seem like I have receiver problems (AGC) or is this normal for the 3B?

Jim,

I don't think that is normal.

Off the top of my head, is the rig calibrated, especially the second portion? That might make the difference.

In my experience, if my K2 can hear it, my ATS rigs can hear it.

--- In AT_Sprint@yahoogroups.com, Michael Harnage <w1mt@...> wrote:

Jim,

I agree with Mike. The ATS rigs are very sensitive. You can hear 0.1 microvolt - or less - once the filters are right. However, AGC doesn't work until the signals are moderately strong, so the ATS rigs differ from some of the commercial rigs with lots of RF/IF gain and heavy AGC action.

This means we use sensitive phones so we can hear the weak guys - they're there - and then we need a volume control to knock the audio back to a comfortable level when a strong station comes on. An audio gain switch with two positions would be OK also.

Some headphones are very insensitive. The ATS rigs want to see something between about 8 and 65 ohms, more or less. The two headphones are put in parallel (mono), so the effective load is half the value of each earphone. The DC resistance is a pretty good approximation of the audio impedance.

If you don't hear signals of medium strength loud in the phones, something may be wrong. Without more information I'm only guessing.

Folks:
I am currently using some 8 ohm headphones of unknown origin with my ATS3. As I am losing my hearing slowly but surely, I want to get a pair of the most sensitive phones that I can find. I would prefer to type that fully encompasses the ear, the padded ear cup type. I really don't like the walkman types, and the in ear ones drive me nuts. Ant suggestions out there? I am sure that some of you have done a thorough investigation of this.

My dream 3b has a little audio amp built into that space next to the rf connector. There's some serious real estate just languishing there! Then a thin speaker could find its way into the tin, too. That would also boost headphones when necessary. I can tolerate headphones just about 10~20min, then I have a headache. Also the amplified audio is a bit more family-friendly. Dad sitting there in his own world with his headphones on got old fast.

I have an ATS-3 and I had to try different headphones to find
something that worked well. Generally speaking the cheap earbuds and
such did not work well. I think Carey is right about the headphone
impedence being the issue - the audio amp in the ATS wants lower
impedence headphones and the headphones need to be sensitive.

One thing to try that will take the headphones out of the loop is to
plug in an amplifed speaker (preferably something with a input level
control). Once you get a good level setting on the speaker, then
compare to another known radio. If you still have problems with the
weaker signals, then the problem is probably in the radio.

On this list or maybe qrp-l, someone had purchased a micro amplified speaker, white, that plugged into an MP3 player. I liked it for its size and that it only used one AAA battery, but it seems it was a clearance item and I couldn't find one.

While cruising The Source by Circuit City, (What Radio Shack has become here in Canada, and its not a change for the better), I found a black one by Centrios for half the price. Same deal, a single AAA battery. It wouldn't plug into the ATS because of the tight plug spacing, so I bought an 8" cable extender with a volume control for six bucks. I find this combo works very well on my ATS. Its not LOUD, but it provides ample volume for these deaf ears. I think it will really come into its own when I get the firmware with SCAN loaded.

I thought about the headphones too. The walkman-style stereo phones I used are 24 ohms. I also tried a pair of RadioShack communications headphones I had (16 ohm) and the audio was even lower with those. The specs for the LM4808 show ouput figures at 16 ohms and 32 ohms so I think I am OK at 24 ohms.

I went and re-checked the second part of the calibration procedure as suggested and it was OK. Guess I will have to try the bright light and magnification check around the audio section. But not tonight, it was a warm California day today and it is still 84 degress in the shack!

Do you have the same problem on other bands?

The RF signal needs to pass through the toroids on the filter board.
One common problem is a failure to make a good solder connection to
the enameled wire of the toroid (typically, from not stripping the
enamel back far enough). On the bare filter board your ohmmeter
should show a short circuit from P6 to P4 (the low-pass transmit
filter, also used in receive), and each contact of the transformer and
LF4 (the RF choke) should show a short circuit to ground (P5).
Another possible error is to get the transformer windings mixed up --
the two ends of the short winding go in the inner two holes, and the
two ends of the long winding go in the outer two holes. This can't be
checked with the ohmmeter (unless you unsolder something), so look at
it under magnification and push the wires around to make sure you know
which is which.

With no band module installed, can you connect the N0SS noise
generator between pin 1 (signal) and pin 5 (ground) of where the band
module goes? How does the volume compare then?

If the problem isn't in the filter module, the most likely problem is
a poor solder joint on one of the IC's in the receive chain. Connect
a signal source (such as an antenna or your noise generator), and use
a toothpick or similar insulated tool to push down on each pin of each
IC, while listening for an increase in received signal. (You may even
see a pin that moves, but listening is a surer test.) It's also
possible to find a resistor or capacitor in the receive chain with
only one end soldered. Again, good magnification helps.

If signals are there, you should be hearing all but the weakest plenty
loud with just any old headphones.

Good luck!

I was pleased to see (below) that Norcal has come out with their FCC2 Mk II DDS VFO. I was especially interested to see that they appear to get the AD9834BRUZ DDS chip to operate up to 31Mhz. Since this is the same chip that's in the ATS3-B, I am wondering if there is a possibility of adding 10M to this great little rig? I know that Steve provided a convincing rationale for not going this high in frequency, but I still hold hope that it might be possible. Do any of you DDS wizards out there have any thoughts on this?

Subject: [qrp-l.org] Another New Kit From NorCal!! (really an upgrade, but it is neat)
Date: Mon, 9 Jun 2008 21:35:08 -0700 (PDT)
From: ki6ds@...
To: qrp-l@...
CC: qrp-l@...

Bob Okas the genius who designed the FCC-1 and the FCC-2 has done it again. He has upgraded the FCC-2 and it is now known as the FCC-2 Mark II. It is full of new features, and is available right now from NorCal. Go to www.norcalqrp.org and check out the manusl. The selling price without the DDS chip is $40 US and $45 DX. Full ordering details are on the webpage. The FCC-2 has been out of stock for about a month as we retooled to make the improved version available. Bob and his crew have worked hard to make this happen and I want to thank them for their hard work. Dean, Ron, Bob, Paul, Bob Miller and Song Kang all deserve a big thank you for their efforts. Details on the new kit are below.

This is the second generation of the popular FCC-2 introduced in 2006. Recent advances by Analog Devices, the manufacturer of the DDS chip, have enabled increased performance and the latest chip supports a clock frequency that□s 50% higher than the original. This permits the new FCC-2 to produce frequencies up to 31 MHz with the same performance as its predecessor. The firmware has also been enhanced to provide x2 and x4 frequency output, making the FCC-2 Mark II suitable for use with software defined radios which employ frequency division to develop a quadrature LO. Of course, all of the familiar features of the FCC-1 and FCC-2 have been retained.

For those new to the FCC-2, it is an add-on DDS VFO board that extends the basic capabilities of the FCC-1 counter kit. All of the FCC-1 features have been retained, so you won□t lose them by upgrading. A lot of work has been put into this kit to minimize power consumption and permit battery operation for extended periods. Surface mount technology (SMT) has been used extensively to minimize the size and weight of the kit. The FCC-2 is peerless in its low power consumption and flexibility.

The kit features a DC □ 31 MHz DDS (Direct Digital Synthesis) chip, a shaft encoder and provides RTTY support. A new PIC microcontroller is supplied with the kit, which adds the VFO to the basic counter features. The VFO firmware supports 13 bands from 160m through 2m, plus a non-specific, Direct band. There are numerous user-programmable parameters which are stored in EEPROM for one-time setup convenience. You can easily switch between VFO and frequency counter modes and the DDS output will retain its frequency. You□ll see later on how we use this feature to calibrate the counter. The userprogrammable IF offsets and scale factors permit the VFO to operate in a wide range of HF and VHF applications.

Dual VFOs and Split operation are supported in the firmware, and the FCC-2 will operate RTTY straight off your workbench. Just connect a COM port cable and launch the software. I□ve used MMTTY and it works great. You can incorporate the FCC-1/2 combination into a homebrew rig or package them into a separate enclosure for use as a portable test instrument. Typical current consumption for the pair is approximately 70mA. Operation is as simple as connecting a power supply.

The 9834 in your 3B kits is indeed capable of being clocked at 75MHz. Problem is that oscillators at that speed draw more current. It was also hard to find oscillators at that speed at the time Steve started the 3B. They may be easier to find now though, I haven't looked. You might get lucky and be able to run the dds at 80MHz, then you might be able to run 10M if the rest of the circuitry can handle the faster speeds. Probably have to re look at the regulators to make sure that their not taxed too much. Oh yeah, the filter out of the dds might have to change too....

Brian and All,

Finding the right headset to use with the ATS3 is not necessarily easy. Since there is no AF gain control, I prefer to use a headset with an inline volume control. The best earphones I have are Sony brand, and they have the highest sensitivity. Koss makes some good ones too. But since you don't like the "in ear" type, You may be interested in an over-the-ear headphone model I recently found at Tuesday Morning or all places! The brand is Audio Technology, or something like that. But the model number is "AU-541", and if you google that you will find several options of places to buy them. They were dirt cheap at Tuesday Morning--$6 I think. When I googled the model number I found them for around $12, which is still pretty cheap. This model seems to be relatively sensitive, and does have an inline volume control too. I'm reasonably pleased with them, so maybe they would suit your needs.

Since you indicate having a bit of a hearing problem, I might suggest another accessory. For some time I have used a small headphone amplifier (purchased at Radio Shack) with several of my QRP rigs that are a bit anemic on AF output. Radio Shack calls this little amplifier a "Boostaroo", and it sells for about $25. I bought mine on sale for $17 or $18. I've also seen what looks like the identical item under different brand names from other vendors. Anyway, it works great, and also has a built in volume control. This gadget is also very handy for use with my laptop when I am on an airplane. Often the engine noise will drown out the audio from my laptop (and I've found noise canceling headphones only marginally better), but this amp really solves that problem. I would think for someone hearing impaired it would really be a useful item. It's internally battery powered, and the batteries seem to last quite a while. This thing actually has provision for connecting two headphones, so two people

can listen with more than adequate volume. If you buy this unit, you could probably use any set of headphones you want--whichever is the most comfortable. In your situation I'd be more inclined to try this first, instead of a bunch of trial and error on headphones that might disappoint.

Hope this helps.

Get a 25MHz XTAL oscillator. They are common for Ethernet apps. Resonate
it with a LC and extract the third harmonic. Feed a line receiver or
comparator with it. Voila!

I kind of jumped the gun. The chip used in the new Norcal FCC2 DDS VFO is the AD9834CRUZ and not the AD9834BRUZ that's used in the ATS3-B. I am not conversant in what this means, but I wanted to correct my original post.

If the AD9834CRUZ does have some advantage over the AD9834BRUZ, you can get a free sample of the AD9834CRUZ from Analog Devices.

I note that the FCC2 circuit does not use a crystal at all. Whether this relates to their getting an output frequency of 31Mhz, I don't know.

As always, I'm chasing ideas.

The FCC2 Mk2 uses a 75MHz oscillator (it's U3). This limits its usefulness to 25MHz. (In practice it is acceptable to stretch this a little, which is what they have done to get to 31MHz. Steve does the same in the ATS rigs.). AD actually specs it to output 37.5MHz but I believe that you will have too many spurs if you push it that far.

Only diff between the AD9834CRUZ and AD9834BRUZ is the MCLK spec. (B=50MHz and C=75MHz). I believe that the B grade used to be spec'ed at 75MHz because that is why Steve used it in the 3B. Not sure why/when AD changed it.

Notice also that the power draw for the FCC2 Mk2 is 70ma vice 30ma for the original FCC2. Much of that is used by the 75MHz oscillator. :)

3192. Re: [AT_Sprint] AD9834C v AD9834B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-10 22:33:01 UTC
From: Stephen Wandling
Topic: 3183 Message: 3192

Michael,

Thanks for sorting this out. But, I have to admit that I am still hopeful that a 10M ATS rig is possible and reasonable!

I find it interesting that AD has now downgraded the AD9834B to 50Mhz. Steve discusses it as a 75Mhz device in the manual and I wonder if he might have actually tried to get it to work acceptably at 10M, but found that it didn't and lowered his oscillator frequency to 60Mhz to conserve power. If that's the case, then there might be reason to try it again?

If the old FCC2 drew 30Ma, and since the 70Ma figure for the FCC2 Mk II includes the 30Ma for the FCC1, then there is only a 10Ma increase and I am assuming that there might be other reasons than a higher speed oscillator? As noted below, I am not qualified to be wrong on the subject!

I am buying the FCC2 Mk II and will be interested in whether there are any spurs at the high end of its spectrum.

Now, is it possible to build a filter board for 10M and with changes to the firmware (I'm presuming), get the rig to work at those frequencies? I am thinking of this as a test. One might also switch to the AD9834C to see if this helps. Is it as simple as I suggest, or are there other changes that have to be made? I suspect that the oscillator would have to be changed to 75Mhz, and I have no idea what changes that might trigger. And let me be the first to say that I am not setup to do this or am I experienced in this level of electronics. I terminated my formal electronics career in 1967 and apparently much has transpired in the interim. :-)

I am encouraged by the facts that Steve pushed the rig to the 12M band, or about 41% of the 60Mhz oscillator and presumably got a signal with acceptable spurs. 41% of a 75Mhz oscillator gives about 31Mhz. So, with the AD9834C it seems possible to reach 10M and stay within Steve's own parameters.

I will be interested to hear what Steve's thoughts are on this subject.

Just to sort out an error in my calculations at the end of the message below. Obviously, the ATS3-B doesn't yet have a 12M band, with 15M as its highest band. (You can tell I haven't built all of my filter boards yet) So, 15M would be about 36% of the frequency of a 60Mhz oscillator and 36% of a 75Mhz oscillator would be about 27Mhz. Not quite 10M. But close. Higher than 12M.

wrote:

Stephen,

I believe that Steve Weber addressed this question several months
ago - he wrote here about the fact that the DDS really could be
pushed to 28 Mhz out, but the high current was one of the problems.
He also mentioned the spurious signals.

I think you could find his messages(s) here using the search box. I
haven't time right now, but I know he mentioned this - lots of us
would love to have a 10M ATS rig when the sunspots come back and 10M
is open around the world with 5W and a dipole in a tree.

There's always a chance Steve or someone else will decide to build a
dedicated rig for the upper HF bands. A second conversion might be
used to avoid having to push the DDS so high. This has some trade-
offs.

Carey,

Thanks for the tip. I found Steve's message and have copied it below. We live in a world of very rapid changes (Sunspot cycles being a notable exception! :-)) Analog Devices has re-instituted the 75Mhz 9834 and the FCC2 uses a small 75Mhz oscillator.

But I am reminded of Edward de Bono's book "The Six Thinking Hats" that proposed the metaphor of changing hats to structure thinking and discussion. (Most of my books are still in storage, so this is from memory) The blue hat was for "blue sky" thinking: no limits; what if?; etc. The red hat was for voicing objections, the white for 'doing the numbers'; cost benefit analysis, etc. The main point being that he felt it was best if there was an agreement on what hat they were wearing at any stage. It is intended to avoid situations where A says "Let's build a gazortchblatz and B says "I hate the gazortchblatz" and C says "Escher tried to build one and it was impossible". I love de Bono's work. If the world would implement his thinking it would be a much better place.

I want to concede that 10M isn't the hottest of bands right now. That being said, there are probably other things that might take priority over getting 10M operability on the ATS. But that need not preclude a bit of 'blue sky' discussion. The sunspots will come again!

I'm aware that there are only a few on this list that do most of the "heavy lifting", when it comes to the ATS rigs, and I am not interested in increasing their load. Nor am I in any way criticizing the ATS design or Steve's work. I love this rig. I think its amazing. It has definitely set the benchmark for rigs that are small AND full featured.

I confess to being a synergist. I have very varied interests and delight in finding something in one area that might somehow fit in with another. That's just how my head works. Sometimes these ideas are useful and often they're not useful, . . . yet. Timing is everything. For me, its great to have a list like this where I can throw out ideas and get a valuable response. Thanks for being there.

75 MHz clocks don't seem to be commonly available. I tired a 80 MHz clock with a 9834 I had from before AD changed the clock speed spec for the chip and it worked fine. With the 80 MHz clock, I was able to make the rig work on both 12 and 10 meters.

However, there were two issues. One, the rig's current went up to over 50 ma on receive due to the high current of the 80 MHz clock and fast clocking of the DDS chip. Second, the transmitter output filters were very touchy to adjust. Very small changes in the spacing of the wire on the cores made a huge change in output power.

Even though it was possible to make the rig work on 12 and 10, I decided it wasn't worth the current penalty and the expense of yet another two filter boards, especially since it will still be some years before these bands are of much use.

It made more sense to only go up to 15 meters, which only added 10 ma to the current compaired to the 3A and these bands had more chance of seeing use in the near future.

Anyway, I'm working on a small SSB rig which will cover 20 to 10 meters, though at the moment, I'm in no rush to get it done. Just want to have it ready for when these bands start to become active again :-)

3196. No output power

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-11 20:26:21 UTC
From: Andreas Burkart
Topic: 3196 Message: 3196

Folks,

I finished my ATS-3B. The rig worked in the beginning and produced approx 1 W on a 9 V battery. When I powered up the rig last night on a fresh 9V batterty I noticed that I am not getting any power out of the rig anymore not matter what filter board I use.

I can see a signal at the input of U8c (at R19) when keying, however nothing after that.

I wonder if somebody could me some trouble shooting ideas, in specific what to look for. I inspected the solder joints but could not find anything in specific.

It truly appreciate your help.

First two things to check:

1. Use a battery with some power. 9v batteries don't
last long and can't provide the current to tx for
long.

2. Recheck the leads on L3 to make sure they are
tinned correctly and soldered properly. If the enamel
was not removed completely it could cause no power.

If neither of these do the trick let us know and we'll
try other stuff.

3199. ATS-3 problem

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-12 02:19:51 UTC
From: Larry Makoski
Topic: 3168 Message: 3199

Yep,

I have an ATS3 problem. Not a 3A or 3B; but after a few years on the shelf; I finally got to building my ATS3. I finished it last week and got the comforting Morse Code in the headphones; but nothing else.

The voltages on U1 and U2 seem OK as per the chart in the manual. But as I go across R21, I develop a problem. On the supply side of the resistor, I get 4.95V. On the other side, the U3, U4, U5 side, I read 3.0V. Something is seriously bringing the voltage down. I double checked the soldering and component placement and orientation and everything seems nominal. I'm thinking that I have a defective U3, U4 or U5.

Any thoughts would be appreciated.

From: Kurt Savegnago
Topic: 3168 Message: 3201

Hi,

Any word yet on Steve's, KD1JV, status? I expect
some folks are still anxious to hear if there is
another run of the 3b in the offing and the timeframe
to expect its' release.
My interest is purely selfish in that I have a
Small Wonders Labs DSW-!! 40 meter tranceiver that
transmits just fine but my receiver just doesn't work
properly. Dave Benson has Steve listed as the go to
guy who is willing to trouble shoot and fix.
I really would like to get the unit operating
sometime and wanted to make arrangements with Steve to
somehow fit it into his busy schedule.

He's been off the trail for two weeks or so. He posted
on another list a few days ago. He got sick on the
trail and is probably resting and trying to get caught
up to speed on everything.

Did you try emailing him yet?

3203. Re: No output power

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-12 15:17:32 UTC
From: c6alk
Topic: 3196 Message: 3203

Here are some tips:

I had a problem with my ATS 3 like yours, no TX output. I didn't actually build this rig, so wiggled a few components and found that R-15 was not properly soldered. Simply heating up the connection fixed the problem. The connection appeared to be fine, but must have had a hairline crack. Reheating, carefully, connections around. R-13, Q4, R14,C53, C54, R-15, C56, Q5, and the 2N7000's might fix it for you without to much troubleshooting.

The 2N7000's need two signals/voltages to work. One is the RF signal from U7, and the other is the keyed B+ from the NDT2955.

Tracing the Keyed voltage:

When keyed, you should see B+ voltage on the drain pins of each 2N7000. This can be measured at the ungrounded side of C-56. If you see this, then check the signal through the filter board.
If you don't see this B+ switched voltage upon keying, then look at the input of the NDT2955 Mosfet switch. This chip is oddly shaped, and has a large pin on the right, 3 smaller pins on the left. You should see switched B+ (key down, causes voltage)on the large pin (the Drain pin). The top pin of the 3 smaller pins on the left is the Gate pin, the second one down (the middle one) is another connection to the Drain pin. The Gate pin should show Ground on Key down. The bottom pin is the Source pin, and should have +5 volts on it. I am not sure, but I think that this voltage is there at all times.
Tracing back, you should see a ground on key down at the top of R15, both sides of R14, the tops of C53 and C54., the collector of Q-4 (right hand single pin). You should see a 3-4 volt signal upon key down at the base of Q4. The top left pin is the base. The bottom left pin is the emitter, at constant ground. This signal comes from U-10 pin 16, through R13.

Tracing further back for the RF signal:

At the Gate pin of each 2N7000, you should see an RF signal with a scope, Diode RF detector etc.. This also can be see at pin 1 or pin 4 of U-7, a 74HC02. The input to U7 is from U-6, the AD9834. If the rig works in receive, then U-7 should be working OK. If you don't see s signal here, look for cold solder joint between U6 and U7.

When I had my TX problem, I made a hand drawn diagram with voltages and waveforms of all this, so I simply referred to that here.

Hopefully there were no errors in my description above made when I converted the picture into text here.

It is true that one picture is worth a thousand words!

I hope that this helps,

Brian K7RE

Nevermind my previous post, I was looking at an old
schematic where R22 was mismarked as R21.

Check current draw while on to make sure it is within
spec. 25-30ma should be fine. Much more and you
probably have a short somewhere.

Try using a toothpick (or other non conductive item)
to push down on the leads of U5,U4 and U3 while
powered on. Listen to see if the rx becomes active
while pushing on the leads. Sometimes a joint will
look good but in fact be bad. Since you have sidetone
it appears that U5 might be OK, as well as U3b. Double
or triple check every joint in the audio chain from
R21 to L4. You may need to look upstream in the chain
all the way back to U1. Look especially for solder
bridges on the IC's. If you have a scope (or perhaps
an rf probe) check for a signal at R5, C22, C21,
C18/C19, C10, C6 to try and figure out which
IC/components might be the culprit.

My bet is on a bad joint somewhere vice a bad part. I
have never seen these parts be bad, but guess there
could always be a first time.

Btw, if you have an early version (where R22 is 330K)
you will want to change R22 from 330K to 270 ohms.

Folks,

I took your advice and re-heated some of the solder joints and checked
L3.
Additionally I cleaned the board carefully with some alcohol. I
noticed that very small metal shavings from th altoid box bridged
possibly one of the solder connection.

Can you give me a source where you can order the 6 pin SIP socket? I
damaged mine with my my solder iron.

As a next step I will take KX0R's instructions how to optimize the
output power.

I got some 36-pin strips from Mouser Electronics and cut them down to six pins. I used them for storing the other 5 band modules by soldering them to a pad-per-hole circuit board.

Anyway the Mouser P/N is 517-850-01-36, $2.41

http://www.mouser.com/Search/ProductDetail.aspx?qs=kc%2fM%2frumzCVxL43fsku9gw%3d%3d

You can get the strips with other pin counts, check out the page in the catalog: http://www.mouser.com/catalog/634/1329.pdf

When I finished my Bee, I used the alternate method of setting the oscillator frequency, because I didn't have a frequency counter. Yesterday my FCC1 kit arrived and I built it this morning. I thought I would try it on the ATS.

I apply power with Split/Tune Down depressed and get the CF (C on the display). At TP1 the FCC1 reads 10,000,000.080. So I use the Tune Down to bring it to 10Mhz. I press Menu and get the CO and low tone, I press Menu to skip this (I did this before), and the ATS resets. I am under the impression that the frequency is now set at 10Mhz.

But, when I start the process over (power up with Split/Tune Down depressed), to make sure it works, the frequency is back to 10,000,000.080.

I'm running out of ideas. Any assistance will be appreciated.

Stephen:

The defaults are loaded every time you enter calibration mode per Steve's post below, so any previous adjustments are lost.

Jim,

Thanks for this. From reading the series of posts you point to below, I realized that I was also resetting my LO and had to do that again as well.

From: Stephen Wandling
Topic: 3211 Message: 3214

My next level of questioning is: How does one know if their rig's frequency is accurate? Or how does one check their rig's frequency for accuracy?

I have just completed the calibration of the CO and LO. I fire up the ATS on 40M and measure the LO frequency with the rig tuned to the default 7030Khz. It reads 2115.27Khz, but by calculation, it should be 2114.8Khz. If this is the case, then I have an inaccuracy of 0.47Khz. It would appear that the ATS is really tuned to 7030.47Khz?

Leaving everything the same and running the ATS into a dummy load and tuning the IC706, the ATS would appear to be transmitting at about 7029.87Khz. That's a 0.600Khz difference from the calculated receive frequency.

Am I getting inaccurate readings for one reason or another? Or maybe I should suspect my newly built FCC1 frequency counter?

Put the 40m module in and tune to W1AW or CHU (if it's
still there). You should hear the respective main
carriers at 7.0475 or 7.335. If you have my firmware
put the 30M module in and tune to 10.0MHz. CHU is
probably more accurate than W1AW. CHU transmits on
other freqs as well. <
http://inms-ienm.nrc-cnrc.gc.ca/time_services/shortwave_broadcasts_e.html
>

The |tx-rx| freq is 600Hz so that you can have
something to hear. The rig will display (or
annunciate) the freq you transmit on. The rx freq has
to be 600Hz off so that you can create the audio tone
of 600Hz with the mixers.

A note on the calibration. If the calibration was not
reset to the defaults each time you entered cal mode
you could get the rig in a very bad condition with
virtually no hope of fixing it unless you reloaded the
firmware. When I setup a rig I write down the offsets
in a form like this: +13/-5 Which to me means click
up 13 times during CF and down 5 times during CO. This
way I don't have to hook up the rig to the computer
and another radio to recalibrate it. :)

If you haven't tried it, have a look at my cal
procedure at: <
http://w1mt.qrpradio.com/ats3calibration.html > I
wrote it a while ago but the principle still remains
valid. It's what I use to calibrate a rig.

If you have another rig to recv WWV then you can
calibrate the rig as good as your gonna get without
expensive test equipment. Perhaps just as well given
the granularity of the adjustments.

From: Stephen Wandling
Topic: 3211 Message: 3216

Michael,

Thanks for the response.

I am aware of tuning to a known station and have done this from time to time. What I had noticed in general, was that with the ATS, lots of stations were not on an even frequency such as 7030, but would appear to be on 7030.1, or 7040.1, etc. This made me suspicious and is what inspired me to re-calibrate the ATS.

I thought the 600Hz sounded familiar: of course its the offset to allow the CW signal to be heard.

Your scary comment: "If the calibration was not reset to the defaults each time you entered cal mode", needs some clarification, please. I simply entered CF mode, noted that the frequency was 80Hz to 90Hz high and pressed the Tune Down to correct this and then pressed Menu to save. Is there something else I am supposed to do? If so, what?

I understand the granularity in the tuning, but I am not clear why I can't get the ATS to be closer to the displayed frequency than 470Hz. This is my biggest concern and I am unclear if you addressed this.

It was my intention to use a frequency counter with my Bee when I am using it on the bench, much like the QBSA did. It was my understanding that I would connect it to the LO out, and program the counter to reflect the IF frequency of 4915.2Khz. Is this correct.

Michael,

In re-reading your post I note your clarification that the rig displays
the transmit frequency, and not the receive. That would make the
'error' 130Hz, which is better than 470Hz, but its still a concern, and
I would like it to be zero.

Nothing else to do, you're doing it fine. I was trying
to explain why the calibration resets the defaults
for each calibration rather than "building" on what
was already stored for the those constants.

You should indeed be able to get closer than 130Hz.
With Steve's firmware you should be able to get to +/-
10Hz.

Remember that your calibration is only as good as your
frequency source. Few of use have properly calibrated
frequency counters and the best thing we have access
to is WWV. Simple matter to put the WWV (10MHz of
course) signal "on top" of the calibration signal from
the ATS rig using a second receiver and a spectrum
display as I describe on my website. If your ear is
really good you can do this by zero beating the
signals on the second receiver.

Hope this is making some sense.

Thanks Michael,

Its good to hear that I can get to +/- 10 Hz!

I do have a concern about the calibration of the FCC1, which I just fired up and calibrated today. The zerobeat dip is very broad and this gives me some concern. I was using the FCC1's 250Khz output to zerobeat with WWV, as per instructions. I used AM mode to do this, as I do not hear any zerobeat with CW or SSB. This may be the root of my problem?

--- In AT_Sprint@yahoogroups.com, Stephen Wandling <swandling@...>
wrote:

Stephen,

Here's a way to check your counter - crude but easy to do:

If you have a fairly stable oscillator, or generator, warm it up for a while. Then listen with a receiver to WWV or another "standard" station, and tune your oscillator on top of it. You will need to adjust the relative level of your two signals so you can hear a good beat. Adjust your oscillator as close to zero beat as possible, and measure its frequency with your counter. You may be able to use an S-meter to get closer to zero beat if you have trouble hearing the softly varying beat sounds.

If your counter is perfect, you should read out the frequency of the standard station. Any error will tell you how far off your counter is, and in which direction. This may enable you to figure out a correction factor. Even better, if your counter's reference oscillator is adjustable, you can correct it until your "transfer" oscillator reads correct when zero beat to the standard station.

A good transfer oscillator is a VXO - variable crystal oscillator - running near 10.000000000 Mhz. 10 Mhz crystals are cheap and available, and a stable VXO would not be hard to build. I'm ashamed to admit that I need to build one of these for my shack.... If the VXO is done right, it becomes a convenient secondary standard. Similar devices are available on the Internet. Some use calibrated TCXO's.

There are many variations on this theme. It should be possible to get within a few Hz, or closer, using the transfer oscillator and a corrected counter.

I have confidence in the ATS calibration scheme - both my "A" and "B" came out about the same, according to my counter, which has a TCXO reference. My "A" will tune to 10.000000 Mhz, so I can play some games with WWV, a second receiver, etc. I think I'm within 20 Hz or so, but without a good transfer oscillator, I'm fudging.

We're still waiting for someone with a really good counter to measure the drift of the ATS-3B and see how much it changes during a QSO, from cold start, etc.

I have an old Heathkit counter that reads to 1 Hz, but I don't have any solid reason to believe it's any more stable than the "B" - maybe

if I leave it on for a while I could rely on it. The transfer oscillator would settle that question also.

You can see where this is going....

Every oscillator and every crystal has error and drift. You can get control if you find a way to compare and adjust a low-drift oscillator to a standard station, so you have a nice convenient source right there in your shack.

Remember that until recently, most of the small QRP rigs had relatively poor stability and accuracy. The DDS rigs represent a huge improvement. To do better you would need a TCXO reference oscillator. The ATS rigs are precision tools compared to what we have previously used. I have a hunch that even if you set an ATS to 10 Hz, it may not hold that accuracy over the range of common outdoor temperatures, like from 0 degrees F to 100 degrees F. I don't know - I haven't measured mine. I have access to an environmental chamber and a good counter, so I may run a test some day.

It really doesn't matter. The ATS rigs do a great job. They actually run well from below zero F to at least 100 degrees F. To beat an ATS you need a much bigger rig and everything else that goes with that.

Try for 10 Hz...

From: Jim Fraser
Topic: 3168 Message: 3224

Yes, the problem is identical on all bands. I am still confused about U5, the AGC chip AN6123MS. Steve lists the pins and voltages in the documentation as follows:

Pin 1 - 1.3v Audio In
Pin 2 - 0v GND
Pin 3 - 5.0v V+
Pin 4 - 0.34v Vagc
Pin 5 - 0.96v Audio Out

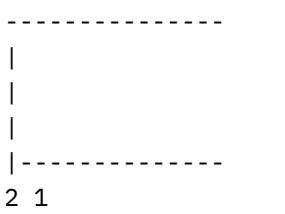
However, the data sheet for the AN6123MS device identifies the pins as follows:

Pin 1 - Vcc
Pin 2 - DET
Pin 3 - Audio Input
Pin 4 - GND
Pin 5 - Audio Out

That the pin functions do not match is confusing. The voltages I read are as follows:

Pin 1 - 5.01v
Pin 2 - 0v
Pin 3 - 0.93v
Pin 4 - 0v
Pin 5 - 1.27v

using the AN6123MS Pinout



Could someone with a functional Bee do a quick measurement of the voltages on this device and report the findings.

Jim K6JF

Jim,

Firstly, in my manual on page 27, Steve has the same data and pinouts that you got from the Panasonic datasheet. Are you using the CD that came with the kit? I don't know where you have found the data that you mention.

So, you do have voltage problems at U5. Pin 2 should have about 0.34V and you have zero. I would check that all of the pins on U5 are soldered well and no bridges, and also check R11 to see that it is a 100k (104) and it is soldered properly. Check the polarity on C56, or see if it is shorted by something.

That's what I would do and you may well have done that. Get the right version of the manual and it will probably reduce the frustration level a bit. I know how disconcerting it can be to find (or think you find) major errors in the documentation when you are troubleshooting.

Good luck and keep us informed.

3226. Re: [AT_Sprint] Re: Calibration Reset

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-15 05:39:20 UTC
From: Stephen Wandling
Topic: 3211 Message: 3226

Carey,

While I wish that my junk box allowed me to whip up a VXO, it doesn't, but help is on the way. I ordered the FCC1 frequency counter a couple of weeks ago, and while it was working its way through the system, they issued the FCC2 Mk II, that I also ordered, which as you may know is their DDS VFO that bolts onto the FCC1.

So, I will have the stable oscillator married to the frequency counter, and they even specify calibrating it with the same zero beating on 10Mhz WWV as you do below. Then you get the FCC1 to read the 10Mhz oscillator, and adjust to get it as accurate as you can.

I'm upping the ante. I want my Bee to be +/- 9Hz!

Thanks for your suggestions.

From: NAQCC
Topic: 3227 Message: 3227

NAQCC Special mW Sprint Tuesday night!
This coming Tuesday evening will be the Special NAQCC mW Sprint.

You must use 1 watt or less output power. Other stations can use any power.

I will refer you to the proper URL:

http://www.arm-tek.net/~yoel/sprint200806_special.html

There you will find all the details as to time, frequencies and also certificates for the winners.

This is a special event, for the month of June, that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate; but you must use QRP/p power levels to compete for awards.

This is a good time for you to earn your NAQCC 1000 Miles Per Watt Award. Come join us and have a real good time!

73 de Dave VA3RJ
NAQCC #0004

Stephen,

My manual copy is from the CD of the first run. Anyway I went by the assumption that Steve's chart is correct in which case I should be getting 0.34v at the Vagc pin whereas I have 0v.

I checked that the pin is not shrted to ground, OK. I pulled out C56 and checked that it is not shorted, OK. I confirmed that R11 is 100K, it is and it measures around 97K.

Since the other pin voltages are good, I can only conclude that the device is bad. I will email Steve with these findings and inquire about getting a replacement.

73, and thanks for your input.

Jim K6JF

3229. Run for the Bacon, 6/15/2008, 6:00 pm

Reminder from: AT_Sprint Yahoo! Group
http://groups.yahoo.com/group/AT_Sprint/cal

Run for the Bacon
Sunday June 15, 2008
6:00 pm - 8:00 pm
(This event repeats every month on the third Sunday.)
Location: Your shack or anywhere

Notes:
This Sunday evening, the Flying Pigs Amateur Radio Club International will be holding its monthly Run For The Bacon. This is a friendly, two hour QRP CW Sprint, which is open to ALL radio amateurs, will last from 9:00 - 11:00PM EDT (0200-0400 UTC Monday).

You may work stations once per band on 160, 80, 40, 20, 15 or 10 Meters. Suggested starting frequencies are 1.812, 3.562, 7.044, 14.062, 21.062, and 28.062 MHz.

The exchange is RST, S/P/C (State, Province, Country) and Flying Pigs membership number. If you're not a member of the Flying Pigs, and would like to be; then please cli

Hi Gang, sorry it took me a while to check in after I got back from the hike. Other than a little chest cold the last week of the trip, it was great.

Since I got back, I finally discovered why my implentation of iambic B mode is so difficult to use. I'd been detecting the "both paddles closed" condition at the begining of a space between code elements. Turns out this is too soon. I have changed it to make the test at the end of a space and this works much better. Now there is much less chance of getting an extra element when you don't want one. I'll up load the new code with this chanage to the files section soon.

If any of you have one of the new PFR-3 rigs (which you might have noticed is basically an ATS rig on steriods)I made the same mistake there and have new firmware for the rig which I'd be happy to reprogam your MEGA48 with. (It also has some new features in it and fixes a couple of other minor bugs)

I do have some more ATS-3B's kitted up, but found I'm sort of some parts so will have to order them (tomorrow hopefully) to complete the run.

3231. 3 Bee for Sale

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-16 21:46:45 UTC
From: WA0ITP
Topic: 3231 Message: 3231

I've decided to sell my unbuilt 3B kit. It's unpacked except
for the processor which has been updated by Steve. I think
the reprogramming had to do with the error that occurred
when quickly turning it off and then back on quickly.

I'm very comfortable on portable ops with my great
performing 3, so I see the 3B as surplus to my needs.

Same as original price from Steve, $190 shipped in US.
Money Order preferred, but will take a check if you can
wait a coupla weeks for it to clear. First email gets it.

Thanx..

I love this radio stuff !

Hi, everyone. Love using my Bee. It works fine w/ 50 ohm dipole, but bought the Elecraft t1 to be able to use it with long wire and shorter antenna lengths. The problem I have is every time I try using the tuner the "E" current overload light comes on on the Bee and there is not enough time for the tuner to tune. Has anyone else experienced this and figured out a solution? Thanks for any help!
Rick, WB#BIQ

Use a 9 volt power source instead of 12 volts during tuneup.

Try using a lower voltage power source to tune up
with.

Some have used a resistor in the power supply line to
limit current. (Removing it during operation).

Hi Rick,

I don't have a T1 ATU, but its my understanding that the Bee needs to see something pretty close to 50 ohms when its tuning; either a 50 ohm antenna or a Tayloe bridge type of circuit. I use a homebrew BLT, which has the Tayloe bridge, that I modified to cover 80M-20M and it works fine for long/short wires and my ladder line fed loop.

I don't know how you might interface with the T1, but QRP kits http://www.qrpkits.com/swrindicator.html sells a Tayloe kit. I'm sure others here might know. Carey, KX0R, on this list has lots of info on the BLT.

I use a T1 Elecraft tuner with my 3B and for portable ops I needed a way to reduce the VSWR the 3B sees while the T1 tunes. I wasn't terribly interested in carrying another power source, so I built a 6dB attenuator. These can easily be built with three resistors. I used a pi network.

It works fairly well, although if I had it to do over I'd use a 10dB pad. The general idea here is that the 3B will see a 10dB return loss, but the tuner will still have enough power to get a proper tune. Once the VSWR after the T1 is low, remove the pad from the 3B antenna port and have fun.

See here for an attenuator calculator:
http://www.microwaves101.com/encyclopedia/calcattenuator.cfm

I used one male BNC and one female BNC to make it easy to put it in line. Make sure you use high power resistors, I used 3 or 4Watters (duty cycle matters).

Cheers,

Gary KM5TY

Hi Jonathan,

Well, you probably don't want to do it the way I did. First I read
Carey's info on mods for the BLT www.qrpkits.com/files/*KX0R*_*BLT*_Mod.pdf

Then I simply doubled the original number of turns on the coil and
links. This is not what Carey recommends and I can't remember why I did
it. So, then I peeled off a few turns at a time and got it to tune 20,
but not 80. Finally I added a SPST switch and switched in 250pF for 80.
It isn't what you'd call engineered, but it works.

Is that a molded inductor, or did you wind up that 250uf yourself? Heck, I might as well do that, too. I've got some cores and a meter.

Although I live next to electronic mecca Akihabara, I have a friend coming over to Japan from the US in a couple weeks and I want him to bring along a resistor assortment. I have picked up the nifty Norcal Capacitor box, and need to kind of lay the foundation for tinkering with a resistor kit. I suppose I only need 1/4 watt axial components for your garden-variety QRP tinkering. Could somebody shoot me a good link for something in the 20$ range that gives the most good components? I see lots on ebay and elsewhere, but can't tell the mediocre deals from the good. A few hard-to-find, maybe a few 1/2 watt, or whatever would be nice. I'm building a good basic junkbox here...
Thanks for any off/onlist responses.

Steve,

Several of us noticed that you chose the BS170 mosfets for the finals
in the PFR-3. These replace the 2N7000's in the ATS rigs.

Please comment on whether the BS170's would be an improvement in
either the ATS-3A or ATS-3B. How do the devices differ in this
application?

The data sheets are very similar. It appears that the BS170's have
more capacitance and better thermal properties - suggests a larger
die. Wonder if they're harder to drive on the higher freq's - must
be some tradeoffs.

3246. DFE while in straight key mode

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-17 15:07:55 UTC
From: w1mt
Topic: 3246 Message: 3246

There was some interest a while back in being able to do direct frequency entry while in straight key mode. This handy for those who may be using an external keyer or computer to do the keying. My latest version just posted this morning on my website allows this capability (3B only at this time). I have moved the button paddle mode dit/dah to tunedown/tuneup. Now all one has to do while in SK mode is to double click the vfo button (enter button paddle mode) then click menu+vfo to enter DFE and use the tuneup/tunedown buttons to enter a frequency. Double click to the vfo button to exit button paddle mode when you are done.

Also, improved the keying. It now acts more like the Curtis keyer (mode B) and Accukeyer (mode A).

Also, improved the accuracy of the battery voltage readout. It now annunciates the battery voltage (before the diode) and is accurate to within 5/100 volt according to my DVM. YMMV, according to the tolerances of R45/R46.

Many thanks to Milan Stejskal/OK1IF and Dave Mertz/WA3OFF for their help!!!

Enjoy,
mike/w1mt

Hi Jonathan,

It was a 250pF ceramic NPO capacitor. I had purchased a bag of assorted NPOs from New England QRP for cheap. I imagine that they still sell them. I just tried a few until it tuned 80M properly.

Mike,

Thanks a lot for this. I knew it would be useful to part time SK guys like myself, but hadn't thought about external keyers or computer keying.

I presume the SPLIT button now called the VFO button? I've only joined this group fairly recently and often feel like I need to read something like "The History of the ATS Rig" or some such article, to get caught up. I search the old messages, but its hard to sort everything out that way.

I've put the June 2006 and June 2008 'cheatsheets' side by side in Excel to see what changes have been made and there seems to be many more than what you mention here. Were there other issues of the firmware in between these two dates? I have the 'stock' firmware that came with my ATS3-B (most recent kits), so its obvious that a lot of changes have been made. Right now its all a bit confusing to know whats been added or removed or re-named or moved or changed. :-)

Thanks again for all of your work to make this great little rig even better.

3251. Re: DFE while in straight key mode

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-17 18:44:31 UTC
From: w1mt
Topic: 3246 Message: 3251

Well, hmmm, uhhhh, where to start...

I have always called the second button "vfo", because it seems to fit better with my firmware functionality. Switching between two virtual vfo's in the firmware, seems to lend itself to calling the button "vfo". Internally in the code, it is called split.

As far as changes from 2006 to 2008. Only the menu'ing has changed significantly. The underlying functionality is still the same. Except of course for the recently added items.

My intent is to eventually go back and upgrade my ats2/3/3a code to include everything that can be included from the 3b. Absent, of course, will be things like battery voltage and led's..... but certainly to include updated menu'ing, keying upgrade, and dfe while in sk mode. I'm in no hurry to do that though, since I only have a ATS3 (along with my 3B) still in house and I am more of a single paddle coder, so iambic modes don't affect my sending. :)

There should be no issues from 06 to now, other than the keying. Most everything else is additions or mods to how things are accessed. I don't know what exactly Steve is doing in his firmware to change the keying. Will be interesting to see if it is similiar to what I did.

I have learned more about how a radio works and about the MSP430 processors than I ever could have in a classroom by tinkering with these wonderful little rigs. I am grateful that Steve has allowed others to develop code for his ATS rigs.

I haven't tried them in an ATS rig yet, but they should work fine. Just remember the Source and Drain pins are reversed from the 2N7000's. Some tweaking of the filter might be required. Using values from the Bee filter, I was getting 6-7 watts out at 12 V! Had to tone that down some for safety sake. Since Doug wanted the PFR to run on 12 volts and put out 5 watts, I figured the somewhat more robust BS170's would be a good idea. So far, I don't think anyone has blown them up yet :-)

Hi;
I'm a bit confused as to where I can connect my newly aquired QBSA
(Thanks, Doug!) frequency input to my ATS-3B.
My manuals, maybe older?, don't show where the best spot is.
I assume that a 10 pf cap will do, as I couldn't find a 4.7?
Where's that sweet spot?
Thanks.

Hi Mike,

I don't have a QBSA, but will be homebrewing something similar and I had the same question you have. It seems from the text that it goes at the LO output point. In the picture in my QBSA manual, Steve seems to have attached the 4.7pF to the right side of L1, probably because it has a big pad and space for another connection.

My guess is that the 10pF would be OK, but that's only a guess.

Hope this helps.

OK Gang;
I'm going to try the pin 20 of the DDS.
If I have problems with that, I'll go to the 2nd inductor output of the filter, through the pin 19 LO chain.
Hope it works.
I remember making the NorCal Cascade with the digital readout that was great in RX, but went blank/squirrely during TX.
But, hey, is for the FUN!

Mike,

If you want trouble-free operation of your QBSA with no degradation of your ATS rig, on all bands, please connect to the ungrounded end of either R16 or C28. This is the signal from PIN 20 of the DDS, which is called IOUTB.

Note that the designation for C28 is what's on the PC board as well as the REVISED schematic dated 9/15/07. Some of the earlier schematics in the manuals had different designators that did not match the PCB, and everyone should use the REVISED schematic with the updated designators so we can be on the same page.

C37 is the same cap, as called out incorrectly on the old schematics.

You should avoid loading the other DDS output, Pin 19, IOUT. It's much easier to solder to the resistor or the cap than to the DDS. Use a short piece of tiny coax to go from the IOUTB point to your connector.

My coupling cap is 4.7 pf. I use 18 inches of small teflon coax to feed my QBSA. I used a micro-size phone jack on my ATS rigs for the connection, but you might choose any other small connector that's convenient and different from the other connectors. I have the same setup on my ATS-3A and ATS-3B, and they both work fine with the QBSA. I'm guessing that 10 pf is OK for IOUTB.

Steve did a firmware improvement for the QBSA that fixed some problems with the displayed numbers. You can find info about that by searching this site.

I'd also suggest getting a piece of real red plastic to mount in front of the display - it will look much better than the orange film.

I think there are photos of the QBSA LO connection on this site in the PHOTOS section - someone posted that.

Remember that the QBSA introduces another level of error into the frequency measurement problem, so don't expect lab accuracy on every band. Do the cal a couple of times carefully, and you may get within 100 Hz most of the time.

Mike,

I just found the photo that N1RX has showing the connection to the IOUTB signal for the QBSA LO signal. Just look in N1RX's photos on this site, and you'll see how he did it. He used a disc ceramic cap and RG174 coax.

I suggest small teflon coax and a leaded 4.7 pf MC cap. If you need a piece of the coax, just send me a SASE.

3263. Help ---- Ats3b part issue

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-20 04:48:28 UTC
From: Garry
Topic: 3263 Message: 3263

I finally got back to the build of my 3b and started the install of the semiconductor devices. Murphey nailed me in short order. OOps, 1 part short! I cannot locate the 74LVC1G3157 (U4). I don't know if I lost it or it was missed while packaging but that's not my concern here I will try to pick one up locally but I am almost dead certain it will have to be ordered and I am not sure what package I need. Can anyone help me here and tell me what package is needed to fit the board? I'm pretty certain that anything larger won't work and I don't even know if it's possible to get one that is smaller.

I searched through the manual but if its there, I missed the parts list and the package type. I got the component off the schematic

Bummer, I was hoping to have it ready for field day but I guess it's not going to happen now.

Thanks and 72

Hi Garry,

Well, well, well. He's alive and well. Good to see you working on the Bee Garry. Sorry I can't ship you the U4. Its the same length as U5, but a smidgen wider and has 6 pins where the U5 has 5. I don't know the technical designation for that case size.

Steve's back so he can ship you one. It would probably be faster than ordering one and the price would be much better. :-)

If you have yours done by FD, I will have mine at FD here. Maybe a Bee to Bee chat?

Hi Stephen. Good to hear from you. I am afraid I have not been on
the group lately. The K3 build and learning curve took me away and
occupied the majority of my disposible ham radio time. I thought
Steve was out on a summer long hike so I suppose I might have read a
few posts prior to making mine but I didn't as you see. A Bee to Bee
chat would please me but by now you can probably run circles around
my CW skills HI.

I havn't been on the paddles for a while. I think all it would take
is getting that Bee up and running to turn my head back to CW. In
spite of the horrible band conditions I still hear some decent
signals from time to time.

I'll drop Steve a private email and see what can be done. I guess I
can get the rest together and then there is all of the band boards so
it's not like I have to leave it sit. I did pick up an altoids tin
today with a nice blue paint job.

I can use my ft-897 if need be but I will need a much larger battery
than I would for the Bee.

The parts list is on Page 14 of the 3B manual:

74LVC1G3157 "CC5R" SOT-6

Looks like it is an SOT-6 package.

First things first,

The paddle plug must be plugged all the way in.

Make sure that the paddle is working. Ports 8 and 9 of
the MPU (U6) should normally be 3.5V. When paddles are
closed they should be 0V (one for dit and one for
dah).

If that's OK we'll try something else...

Groups,
Thanks for suggestions.

Here are more details:
-paddle is plugged all the way in and p8 and p9 go to zero on send
as required;

-all control buttons seem to work;

-the U6 voltages are about 3.27v for pins p5, p7, p8, p9, p10, p21,
p22, and p23;

-the regulated voltage is 3.44v;

thanks,
Dave, ki6aco

I'm thinking that your power supply may be weak. 3.27v
seems a little low. What power source are you using?
If it's a used 9v battery please try something else
with a little more capacity. A brand new 9v battery
will work long enough to get through testing.

I assume you heard the band annunciated at power up.
Do you hear the menu when holding down the menu
button?
If so, then the sidetone is working. Also means that
mute is switching U4 properly.

What does the drain of Q4 do when holding the dah
paddle closed? (Voltage?)

Oh yeah, what is the current drain when nothing is
happening? Let's try to rule out a short somewhere.

I already posted to some of you and I wanted to add these for your viewing.

We will be operating WQ4RP and with our own callsigns on the FD event this coming weekend from Black Balsam Ridge and Sam's Knob.

http://jblevins.org/photos/artloeb/

I will be operating QRP of course and will be using the handkey for part of the time.

I look forward to making contact with those of you on the air. We will be on the HF bands on and off as the bands allow up there.

For those interested we will also be using 2m/70cm/6m with our beams from the top (6,214 feet) and hope to do well this year with the addition of the new bands for us.

Hi All

My unbuilt 3B kit is up for sale. Still un-packed, as I received it from Steve.

With all the things going on, I just don't have the time to build.

Original price $190 (£98.00 GBP) shipped UK mainland UK. Postage at cost else where.

Contact me off list for further details.

Best regards

Dennis G6YBC

More detail.
The 3.27v appears only at pins 5, 7, 8, 9, 10, 21, 22, and 23 of U6.
The regulator supplies 3.44v. So I have a voltage drop across the 47K pulldown resistors, R35, R36, R37, R38, R39,
and R40 of 3.44-3.27v or 0.17v. This corresponds to a current into each of these pins of about 3.6uA in the "off" state.
Is 3.6uA a reasonable value at the pins 5, 7, 8, 9, 10, 21, 22, and 23 of the MPU, U6??

And yes, the band indicator works, and does everything else I can test with the push buttons.

Q4 drain drops a fraction of a volt for second or two holding the dah paddle closed; there is
no drop at all with the dit paddle closed.

Dave

Dave,

Did you ever confirm that you have the paddle plugged in when you power up the rig?

That only makes a difference when you want to use a
straight key. You can plug a paddle in at any time.
Course you're likely to get an inadvertent dit or dah
as the contacts short as you plug it in, but it should
be fine. :)

Still bugs me that you don't have 3.5v at the ports.
What is you power source? What is the current draw
with power on but nothing else occurring?

Garry:

Hope you find a replacement and get on the air for Field Day. I am also hopeful to work my 3B on Field Day, but I am waiting for a replacement Audio AGC chip from Steve. I could work it as is but the audio is very low.

--- In AT_Sprint@yahoogroups.com, Michael Harnage <w1mt@...> wrote:

Dave,

1) Do you hear the sidetone with dits and dahs?
2) If you have some response at Q4, but not corresponding to all the dits and dahs, your problem is upstream.
3) Please answer ALL of Mike's questions about the power supply, the current draw, etc. Your answers will help steer the analysis. He needs to narrow down the problem.
4) Based on the limited info we have, it sounds like a power regulation issue, or a failure because some connection(s) are open or shorted.
5) Please get a really bright light, and some kind of strong optical magnification, and inspect your board, particularly the circuits near and around the processor. Look for a leg not soldered, a difference in appearance, a part not soldered at one end, a solder bridge, etc.
6) If you can do it, probe the circuit while you do your inspection. See if the voltages correspond to what you would expect based on the schematic. Be careful not to slip or short between any pins.
7) Measure the current in the supply line to the board, both on receive and when trying to send, and see if it's pulsing, how much, etc. Please use a stiff power supply for these measurements. A regulated, current-limitied supply is best.

If your visual inspection doesn't hint at the problem, your measurements will lead to a line of inquiry that will solve your mystery. This rig isn't as complex as many, even though it's clever and sophisticiated in what it does. You'll get this figured out.

While I don't have the technical background of Mike or Carey, I want to question why you have 3.27V on pin 5. The watch crystal is tied across 5 & 6 and their voltages should be 2.7 & 1.7 respectively. What is the voltage on 6? I believe that the watch crystal is used in the keyer circuit? If that is correct then a high voltage on one side of the crystal would seem to be linked to no keying?

Mike has cleared up my misconception that the paddle had to be plugged on power up, and thank you for that. I throw out the above in the spirit of learning. Who know what I will learn. :-) If I was a guessing man I would be looking for a short between 6 & 7, but that's probably because I don't know the interior architecture of the chip, so it would be a way to get high voltage on the crystal.

3285. AT audio amp and batteries

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-23 11:55:22 UTC
From: Dale Putnam
Topic: 3285 Message: 3285

I've a "too large" stock of recharageable 9v and AA batteries, I use them for the AT rigs. Email me off list for prices, or make an offer. I also have some very nice alkaline AA batteries, that are much better than the ones bought at the stores, in that they last longer, the AT rigs produce rated power with them a number of hours/days longer, of course your results may vary, depending on current demand.

I also have been working on an audio amp drop in for the AT rigs. I've tried a PC board, and a simple "dead bug" arrangement, for space and weight, the dead bug wins.

I have enough parts to either kit up 3 of these, or build them and send them out. They have a volume control add, that doesn't have to include an extra mounting hole, however, that has advantages too. Please state which you want. If there is enough interest, I would order more parts and do it again. More details? Just ask, I'll post more details. No problem. Simply no time now,
Thanks,

I will be doing a very laid back FD with W0WN. We plan to be QRP 1 or 2B. I have 3 riding mower batteries charged up with solar power. The rigs will be a K2 and a K-1. I will arrive Thursday night, so will be playing with the ATS3 prior to the FD event on Friday. We will be in WY, at the Bear Lodge campground. This is located on a hill in NE WY. With at least 2 QRP CW stations on, maybe folks will not be dissapointed by not hearing WY in the event. Although SPC multipliers don't count in FD as we know, lot's of groups enjoy trying to WAS.

One more thing to test.

Enter alternative paddle mode and see if the tune up /tune down buttons
send dits and dahs. Let us know.

Dale:
Sure, would love to share results with you and all who might be interested. I'll try and make a few HFPack type roving QSO's with thw ATS3 on Friday before the contest begins on Saturday. I will also be on 6M SSB with my ancient IC-502 QRP SSB rig. It will do CW, but I am somewhat embarassed by the huge chirp!

I'll make it all the easier to find you!
I'll look for you Friday PM on 6m SSB/CW ...once I'm setup!

Subject: [AT_Sprint] ATS 3B For Sale
From: "g6ybc" <g6ybc@...>
To: AT_Sprint@yahoogroups.com

? ? ? ? ? ? ? ? ? ? ? ? ?

Hi All

My unbuilt 3B kit is up for sale. Still un-packed, as I received it
from Steve.

With all the things going on, I just don't have the time to build.

Original price $190 (?98.00 GBP) shipped UK mainland UK. Postage
at cost else where.

Contact me off list for further details.

Best regards

Dennis G6YBC

Hey.... if we work this right.... and if Murphy plays nice..
we could do an AT to AT to AT Q... at least a Qrp to Qrp to Qrp... maybe before it all kicks off...
Brian, I'm looking for the headphones,
Steve, I will be attempting a bit of a Q or two
with a mobile antenna too. Likely listening more than not.
Good luck to all,--... ...--Dale - WC7S in Wy

3294. SSB reception

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-24 23:50:27 UTC
From: Stephen Wandling
Topic: 3294 Message: 3294

This probably won't be news to many of you ATS owners, but my understanding that you can't copy SSB on the ATS has been shattered. I fell asleep on the UP button while tuning 40M and flashed by something. Backing up I found an Alberta SSB Net in progress. The copy was poor, primarily because of the tight filtering on this rig. But parts of it were quite readable.

I gather that the 'wrong sideband' doesn't apply to 40M? Does it only apply to 80M? If this has been covered in other posts, please point me to them. My interest is being able to check in to SSB nets with CW. One question I have is: "Is there a safe and easy way to bypass the filtering enough to enhance SSB reception?".

Hi Stephen,

Go to Wide on the AST3 and you can work cross mode just fine on 40. But not on the A or B, they do note have the wide filter setting. The filters is wide enough for double sideband and the freq readout will be indicate 600 cycles lower than the transmitted signal.

Thats one reason I've kept my 3...

I love this radio stuff !

Terry,

Is this a firmware thing? I came into the ATS world just recently, so I am not aware of the changes from one version to the next. Do you know how they accomplished the Wide filter setting? I know the B has both the IF crystal filter and an audio filter. The sound I was getting was very much like what I hear when I switch to SSB on my IC706 and forget to switch my Scaf filter off.

Is 40M the only band where this works on your ATS3?

Yes it is, it's in the manual for ATS3, page 7, see below. Its the 8th menu item. .

Steve bypassed the IF filter for the Wide reception option in the first ATS3, but had to remove that feature in the A and B due to needing board space (and probably program bytes also) for other things. I think it is a good feature, and KL7R (SK) used it to check into 80M nets in Alaska..
He's the only builder I knew of that mounted his board "upside down" in the Altoids. He asked for a special label. He was a very nice man and an inventive ham. He left a big hole in hamdom..
http://kl7r.ham-radio.ch/

Have fun with these little rigs, they're special..

Wide Band Reception Mode: (W)

In Wide Band Reception mode, the IF crystal filter is bypassed. This results in double

side band reception. Both SSB and AM signal can be tuned in. In this mode, signals are zero

beaten at the BFO offset frequency. Return to narrow band CW reception by accessing this

option again.

NOTE: While in Wide Band Mode, the AFA will read 600 Hz low, as your now tuned to the

BFO oscillator offset frequency and this is not corrected for.

Yes, I have an AT Sprint 3 (not the "A" or "B" version).

The 'W' menu item disables the narrow passband filter, and makes
it possible to hear SSB signals very easily. I used that feature
on a few occasions to check into the Texas Traffic Net, an 80m
SSB net. The feature works very well.

The Elecraft KX-1 has this feature, also.

I think that feature could be very useful for ARES-type
operationing, or backpacking.

Regarding SSB reception and cross mode operation with ATS rigs.

The ATS3 does support cross mode operation and SSB reception. It did this by doing two things.

FIRST: It switched out the crystal filter providing for a wider bandwidth to allow listening more comfortably to SSB.

SECOND: It calculated where to transmit so that the SSB station could hear the signal.

Post ATS3 rigs don't have the capability to switch out the crystal filter and it's probably not a good idea to jumper them out as the impedance transitions (if that's a concept, hi hi) would be way out of whack. This is why the calculations to put the transmit on the correct freq while in wide mode no longer exist -- there is no wide mode.

Solution 1: One could add a wide mode that would do the calculations but not do the crystal bypassing. This would result in poor audio but cross mode would be possible.

Solution 2: Use xit mode (or split if using my f/w) and manually do the same thing as the calculations would do.

80M - set your Tx to 1200Hz lower than Rx
40M - do nothing, Tx already on the SSB signal
30M - no SSB here so ignore.
20M - set your Tx to 1200Hz higher than Rx
17M - set your Tx to 1200Hz higher than Rx
15M - set your Tx to 1200Hz higher than Rx

I think I've got this right...

Hi Mike,

This is all pretty interesting to me.

You mention switching out the crystal filter. I don't know if it is a new addition for the latest version, but the 3B also has an audio filter. Do you feel that this also contributes to the poor SSB reception? I guess what I'm asking is whether switching out the crystal filter and leaving in the audio filter would actually result in readable SSB?

Thanks for the explanations and your work-around. I'm trying to get my head around why 40M already has the transmit on the SSB signal, and then transmit has to be 1200Hz lower on 80M. Can you shed some light on that please?

The ATS3 had basically the same audio filtering. Yes, switching out the crystal filter does make a difference in the quality of listening on that rig.

>
> I'm
> trying to get my

Fro the ATS rigs, the Rx offset for 80 is on the high side but the SSB is lower side, so you have to subtract 1200Hz (basically 2x 600Hz sidetone).

For the ATS rigs, the Rx offset for 40,30,20,17, and 15 meters is on the low side. On 40M the SSB is on the low side (same side). Therefore no change for Tx freq. While on 20,17 and 15 SSB is on the high side, therefore the need to add 1200Hz.

Hope this makes sense.

3305. Touch Paddle Option for ATS-3B?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-25 23:42:32 UTC
From: Jeff T. Casey
Topic: 3305 Message: 3305

Hi gang,

Does the ATS-3B come with a no-moving-parts touch paddle, or is this available as an option from Steve or from some other vendor? Or is the touch paddle a device that people are building from scratch to go with their ATS-3Bs?

I also have a more general question about touch paddles: Is a special circuit required to convert the capacitance fluctuations picked up by the dit and dah contacts as one touches them into digital, binary form? If so, is this an active circuit, requiring a power source?

Thanks very much & 73,
Jeff

The Touchkeyer in mine was from
http://uk.youtube.com/watch?v=yqnt2zUpJcw , with photos of it here:
http://www.flickr.com/photos/jonathancharles/2291300160/

I am more on the non-technical side of this group--and I had no
problem installing it. Although it is not my main method of producing
CW from the ATS3B, it has save a couple QSO's when such-and-such
happened and I couldn't key with my NB6M PCB-board paddles.
I got on the cover of Make Blog and won a month of flickr pro
(audience chuckles) for uploading photos of it. I still have to lick
my thumb to make it work well beyond 92% of the time.

It fits nicely under the lid of your standard-issue Altoids mint tin.

> device that people are building from scratch to go with their ATS-3Bs?

It was discussed here couple of times. You could either build it from scratch or buy a kit from http://www.cwtouchkeyer.com/.
The chips he is using are QT-113H. If you buy two of QT-113 non-H chips, you will save two 2n7000 FETs. Just build the circuit according to the datasheet. Also the circuit generates short "hartbeat" pulses on the output line. I believe they are filtered out by 2n7000 high gate capacity in cwtouchkeyer.com construction. The pulses are filtered out by debouncing capacitors in ATS-3.

I built mine on a piece of prefoboard and glued it next to the antenna connector. You will find the picture in photos section of this group. The sensitivity is dependent on the capacity of paddle contacts to ground. If you glue pieces of PCB right on the tin like Johnatan did, the zero capacity will be very high and the circuit sensitivity will not be sufficient. I decreased the zero capacity by placing a piece of plastic between the electrodes and tin.

> I also have a more general question about touch paddles: Is a special circuit

It is a pretty smart circuit, that measures capacity and compares it to a long time average. Therefore it calibrate itself.

3310. Re: [AT_Sprint] Re: SSB reception

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-26 02:40:57 UTC
From: Stephen Wandling
Topic: 3294 Message: 3310

Here is my research report after studying the ATS3 and ATS3-B receiver circuits. Nothing much seems to have changed in the crystal filter, with the exception that the series input/output capacitors have been changed from 150pF to 100pf (in the B). The output of the first mixer was an IF transformer and now is a choke.

The switching was done with two SPDT Analog Switches in series. The switches switch out the crystal filter and insert a 22pF capacitor in its place. The Analog Switches are controlled by the Sidetone, which I have to assume is turned on by selecting Wide mode. You do not hear the sidetone in the audio out when receiving, because Mute is not on.

Steve used two Analog Switches in series because he did not get sufficient isolation with only one. It would appear to be simple enough to simply install a manual SPDT switch to replicate the action of the Analog Switches. It would involve a 22pF cap and the switch. Modifying the board to accept this switching may not be trivial. The frequency offset required for each band would have to be set manually with XIT as Michael has outlined below.

Unqualified concerns I have are in regard to possible problems surrounding the leads from the board to the switch. Might they pick up unwanted signals and cause distortion?

Another approach would be to basically replicate Steve's original two Analog Switches and control them through the Sidetone as was done previously. This would entail a very small sub board and modification to the firmware. If a firmware mod was undertaken to do this, it would make sense to also include the frequency offset function that was described below.

Well, that's what I have learned and what I have seen as possible avenues to get this capability with the ATS3-B. I am open to corrections and other ideas. I'm severely tempted to shunt the crystal filter with a 22pF cap while tuned to a SSB signal and see what happens. Only fear keeps me from doing this. :-) Maybe after FD?

Hi folks,
I want to mention a thought, when thinking about mounting the touch keyer kit, you may consider any other add on circuits, or items, like a surface mount speaker. So... mounting the keyer kit, close to the edge of the lid, and above the switches, would improve the chances for mounting additional things... like a 2.5 watt ic audio amp... with vol contol. I'm investigating a speaker too. Haven't gotten there yet, tho.

Hi. My rig is now operational, and with 12Volt it gives 4.7Watt output
at 80meter, and that is 70.6 % power efficiency :-)

The only problem I noticed during calibrating of the ref. osc. freq.
at 10MHz, is that it will not store after adjustment clicking "menu".

The osc. ref. freq. is default almost there, but if anyone can see
what is the "store/save"problem, please let me know.

72,
Tore, LA5TOA
Norway

? ? ? ? ? ? ? ? ? ? ? ? ?

Hi All

My unbuilt 3B kit is up for sale. Still un-packed, as I received it
from Steve.

With all the things going on, I just don't have the time to build.

Original price $190 (?98.00 GBP) shipped UK mainland UK. Postage
at cost else where.

Contact me off list for further details.

Best regards

Dennis G6YBC

3314. Re: [AT_Sprint] Store the adjusted ref. osc. frequency

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-27 17:33:56 UTC
From: Stephen Wandling
Topic: 3312 Message: 3314

Tore,

Congratulations on getting such good performance from your rig. I'm sure you will enjoy this amazing transceiver.

Regarding the calibration not storing, you are having the same questions that I had. Apparently, the settings are stored. But, if you are like me and want to check, you might do the calibration again, expecting it to be as saved. But, I am told that each time you enter the calibration mode, the settings are reset to the default values. You just have to trust that they are saved! :-)

Thanks for your answer Stephen, that was good news for me.

I have used many hours (almost a year) soldering this tiny parts one after one..
Now I have to learn CW in proper speed..

Have a nice summer, and thanks again.

72,
Tore, LA5TOA

3316. QBSA instability

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-06-30 20:07:56 UTC
From: ak3f
Topic: 3316 Message: 3316

i'm using my 3b with a qbsa. the frequency counter function used to work very well and was stable. over the last few months of operation, however, the qbsa's ability to lock on and present a stable display has been getting progressively worse on the higher bands (15 and 17). over the weekend it really became a nuisance on 15, jumping 10's of khz at a time. no problems on other bands.

i wonder if anybody has seen anything similar. any insight is greatly appreciated.

thanks,
mike - ak3f

3317. Re: SSB reception

Yahoo group: AT_Sprint (2002 — 2008)

From: w1mt
Topic: 3294 Message: 3317

I think I should clarify. :)

Only if you bypass the IF filter and tune the SSB signal so that you can hear it clearly will the offsets given below work. 40M is the special case. If you can hear the SSB signal on 40M in the IF passband of the ATS rig, your transmit freq will be OK for the other station to hear you. (By changing the firmware one can make 80M do this as well.)

I really should have combined Solution 1 + Solution 2 below. You can't do Solution 2 with out Solution 1 except on 40m.

>
> SECOND: It calculated where to transmit so that the SSB station could hear the signal.
>
> Post ATS3 rigs don't have the capability to switch out the crystal filter and it's probably not a good idea to jumper them out as the impedance transitions (if that's a concept, hi hi) would be way out of whack. This is why the calculations to put the transmit on the correct freq while in wide mode no longer exist -- there is no wide mode.
>
> Solution 1: One could add a wide mode that would do the calculations but not do the crystal bypassing. This would result in poor audio but cross mode would be possible.
>
> Solution 2: Use xit mode (or split if using my f/w) and manually do the same thing as the calculations would do.

3318. FD '08 on 2-Scoops of Grain

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-07-01 22:55:32 UTC
From: Steve Galchutt
Topic: 3318 Message: 3318

Kinda off topic but I had the ATS along as back up??

Field Day 2008 via QRP, Goats and Solar power was PRICELESS!

Although Es openings on 6m were not abundant if at all at least HF performed pretty darn good considering a SF of only 66! Location was our usual favorite spot a top Mt Herman at 9054' ASL with 1500' shear drop off looking East. Weather was a perfect 70F and sunny with a light shower on Saturday PM.

Maybe it was my location and/or antenna but I felt like I was running QRO as I could easily get through on the first or more often the second call on CW ...most of the time. But SSB was a different story and required more skill, timing and strategy. Calling loud stations or stations that were going unanswered or in the clear. 20m was the most productive and 40m late PM was rolling thunder with lots of big signals.

Goats did their part of getting our nearly 100lbs of FD/camping gear to the mountain top but were very unimpressed with the FD activities and napped most of the weekend. Between the rain, wind/tarps, camping chores and goat sitting I only made 150 QSOs (120-CW and 30-SSB) but it still made for a unforgettably FUN FD!

N0TU (1B)Station setup:
Rig: FT-817, ATS3A as backup
Ant: 10-40m jumper dipole w/40' coax at 25' at edge of cliff, 2m/70cm 5el Elks beam
Power source: (2) 7AH SLA batteries & solar panel
Price to get there: 2-scoops of gain and Rooster & Peanut (goats) ...not bad considering the price of gas these days! In other words, PRICELESS!

Cheers, Rooster & Peanut (and OG Steve/n0tu)
http://n0tu.blogspot.com/

YouTube video tells the rest of the story:
http://www.youtube.com/watch?v=pX2r0ddUqsw
Note: it's mostly about the goats and FD camping!

3319. Battery read out problems

Folks,

My battery read out function doesn't work correctly ! It basically shows the same read out over a wide range of different battery voltages (6,9,12V).

I wonder where I could start trouble shooting ?

Thank you for your help.

Andreas

3321. Re: Battery read out problems

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-07-03 18:10:18 UTC
From: Dave
Topic: 3319 Message: 3321

The components associated with reading the battery voltage are R45, R46 and pin 19 of the processor. The problem is probably around those, since I don't think you could upset the voltage feeding the processor enough to cause a problem for its internal reference without causing the processor to stop working altogether.

I would expect a problem with this circuit to manifest itself as always near maximum voltage (20.4V?), always near zero volts, or some reading in roughly constant proportion to the actual voltage.

Subject: [AT_Sprint] Yes, I'm back...

Hi Gang, sorry it took me a while to check in after I got back from the hike. Other than a little chest cold the last week of the trip, it was great.

Since I got back, I finally discovered why my implentation of iambic B mode is so difficult to use. I'd been detecting the "both paddles closed" condition at the begining of a space between code elements. Turns out this is too soon. I have changed it to make the test at the end of a space and this works much better. Now there is much less chance of getting an extra element when you don't want one. I'll up load the new code with this chanage to the files section soon.

If any of you have one of the new PFR-3 rigs (which you might have noticed is basically an ATS rig on steriods)I made the same mistake there and have new firmware for the rig which I'd be happy to reprogam your MEGA48 with. (It also has some new features in it and fixes a couple of other minor bugs)

I do have some more ATS-3B's kitted up, but found I'm sort of some parts so will have to order them (tomorrow hopefully) to complete the run.

For those who aren't ARRL Members, you're missing a GREAT article by Steven Weber, KD1JV, in QST, August 2008, page 33ff.

Very well done article. For those who are members, lettuce vote for this article to be the ARRL Cover Plaque Award - it's a members-only page, http://www.arrl.org/members-only/qstvote.html

Note that Steve describes how to construct this for <$50 "dead bug" style, but it might be worthwhile to think about the Hendricks kit version - which contains all the parts plus a nice cabinet. See http://www.qrpkits.com/mmr40.html for details.

Note that I have no commercial interest in this article nor in Hendricks QRP Kits.

Dear OMs

I have finshed my ATS3B, and he works sofare very good.

The only problem i have is: As soon i operate a tuner to matsch a antenna, the high current protection goes active. (@6 volts up to 13 volts.)

The avrg. current consumtion in TX mode is apprx.500mAmps.

3327. Firmware update

Hi Rolf,

You are way ahead: Got my ATS-3B kit a week ago. Have placed all R and C, started with semiconductors today...

Your question has been discussed extensively here in this forum. Possible workarounds are:

- during tune-up, insert 10 ohms into the power supply line

- during tune-up, insert a 10dB attenuator between the ATS-3B antenna output and your tuner

- use a tuner which protects your TX from seeing a high SWR, such as this one: http://www.qrpproject.de/ZM4.html

Rolf,

FB on completing the ATS rig!

If you haven't checked it out yet, give a good read at:

http://w1mt.qrpradio.org/ats3.html

There is a cheaper parallel interface (search the archives here). If you don't have a parallel port, you can use a USB JTAG cable from Olimex.

NAQCC Sprint Wednesday night!
This coming Wednesday evening will be the monthly NAQCC Sprint for July, 2008.

I will refer you to the proper URL:

http://www.arm-tek.net/~yoel/sprint200807.html

There you will find all the details as to time, frequencies and also a special prize (a classic book in Morse on CD donated by Chuck Adams K7QO).

This month's Special Award goes to the winner of a drawing among the following: The member in each division who makes the highest score among those who have never before sent in a report for one of our sprints and makes 5 or more QSO's in this sprint.

This is a monthly event that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate (this includes QRO); but you must use QRP power levels to compete for awards.

Come join us and have a real good time!

73 de Dave VA3RJ
NAQCC #0004

3331. KD1JV off-line again

From: Bruce Beford
Topic: 3331 Message: 3331

Hi Guys. Got to spend the weekend with Steve, KD1JV at Lobstercon over in Maine. He is headed back out on the trail for a while. According to his website, there are about 20 ATS-3b's available. But- he won't be filling any orders until he returns, in about 3 weeks time.

73,
Bruce N1RX

From the qrp-l mail-list:

Date: Mon, 14 Jul 2008 21:22:59 -0400
From: Steven Weber <kd1jv@...>
Subject: [QRP-L] Going hiking
To: qrp-l@....net
Message-ID: <3.0.6.32.20080714212259.00aa3c08@...>
Content-Type: text/plain; charset="us-ascii"

I'll be off hiking on the AT again, leaving tomorrow AM. Will be doing NJ to VT, about 300 miles hopefully, if the heat don't kill me.

Therefore, if there are any PRF-3 chips in the mail there will be about a 3 week delay before they get taken care of. Everyone I've gotten so far is on its way back.

Sorry, no rig in the pack, its too heavy as it is!

72,
Steve, KD1JV

3332. ATS(-1?) alive in Sweden!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-07-15 12:43:56 UTC
From: Per-Arne Asp
Topic: 3332 Message: 3332

Hi gang!
Just finished an old ATS(-1?) thats been laying around the shack unbuildt for about 5 years. I think it is the first ATS from Steve as the CPU is Atmel 2313.

Rx seems to work OK on 40-30-20. Tested it during weekend on my home antenna (42m EFHW). Added some suggested mods from N5ESE.

Back at my work (selfemployed) I hooked up 10 x 499ohm in parallell to get a dummyload. Measured output voltage (peak-peak) over the dummy at some different supply voltages:

Vsupp = 12 V
@7040 kHz: Vpp ~ 46.5V => 5.5W
@10110 kHz: Vpp ~ 47 V => 5.6W
@14060 kHz: Vpp ~ 45 V => 5.2W

Vsupp = 9 V
@7040 kHz: Vpp ~ 33.3V => 2.8W
@10110 kHz: Vpp ~ 33.4V => 2.8W
@14060 kHz: Vpp ~ 32.5V => 2.7W

Vsupp = 8 V
@7040 KhZ: Vpp ~ 30V => 2.3W
@10110 kHz: Vpp ~ 30V => 2.3W
@14060 kHz: Vpp ~ 28.5V => 2.1W

Does theese figures agree with what you have got? Is there much to gain if I tweak the inductors on the differnt filter boards? What do you say experts?

Good Afternoon Per-Arne,

First I'm no expert, just a happy ATS3 owner, but there are indeed some real experts who hang out here.

Those numbers are higher than my ATS3 which is 2.5 - 3.5 Watts with 12 volts. I havent tweaked my LPFs or done any other mods.

I believe your finals are similar, if not the same as, Steve's other 2N7000 final circuits. If so then 5 W or more is pushing the limit a little. Ok for operating into a well matched load, but marginal while tuning. You might consider an absorption bridge SWR indicator or adding a 10 ohm or so current limiting resistor in the Vcc line for tuning purposes like some of the 3B owners do.

Sounds like you've done a fine job on the ATS1, congratulations.

I love this radio stuff !

Hi P-A,

No advice on the power output issues though the numbers do seem a little high - could be due to spurs in the output, i.e, you aren't seeing clean power out.

One other bit of advice - be careful handling the modules for the original ATS (I still have one as well). The pins are easily bent if you don't get the modules lined up just right over the sockets. If I used my ATS more, I'd replace the sockets and pins with something more like IC headers and sockets - that would make them a lot sturdier. Also, there is/was a mod or two for the ATS that overcomes some issues. N5ESE had them documented on his page at http://www.io.com/~n5fc/atsprint.htm - he has some performance info there as well.

Enjoy es 72 - john - n0hj

Hi John.

I have done all of the N5ESE mods except adding 1N4148's in the TR
switch(es).

I also see that N5ESE have similar output values to those I have, abt
5.5W @ 12.55 Vsupply.

Thanks for the advise on the filter pins, I noticed that they indeed
looks fragile.

Now, it will be exciting to try the rig IRL! Will do it tonight with
my 42 EFHW at home...

I am confused by your measurements and/or calculations. I use a formula
that says power equals the Vrms squared, divided by the resistance.
46.5 Vpp = 32.88 Vrms. Measured across 50 ohms would equal about 22
watts. You show show 5.5W.

Or am I wrong in my calculations?

Date: 2008-07-15 17:21:36 UTC
From: spitleaf
Topic: 3337 Message: 3337

Hello!

First off a short precentation. My name is Alexander Edblad and I live in Sweden. I'm not a licensed amateur yet but hopefully soon. At the moment I'm learning CW, which will be the mode I'll be operating. I think I can say that I know the code, but need some trainig before hitting the waves. Today I mostly listen to texts at 25-30WPM, just for learning.

Well, to my question. I read somewhere that it's suggested to start with the semi-conductors. Do you guys have other suggestions? Another thing I wonder is how you protect these components from static electricity. I do have a wrist strap but I find it VERY annoying wearing it while soldering.

Thanks,

Alexander

3338. 2008 Alaska ARRL convention station W1AW / KL7

2008 Alaska ARRL convention station W1AW / KL7

A ham radio Special Events Station will be on the air from Alaska's Arctic Circle at 66° 33' North LAT (Grid Square BP56) at the intersection of the Dalton Highway, 200 miles north of Fairbanks Alaska.

This station will be a good test of some of the ARES equipment owned by the Anchorage Amateur Radio Club. We are sending our Club/ARES Power and tower trailer as well as our SteppIR antenna system up to the Arctic Circle over 550 road miles north of Anchorage. ICOM is a major sponsor of the ARRL Convention event and will provide the radios. This event is being done in cooperation with Fairbanks area ARES and ham clubs and will be a good work together effort.

I am hoping to encourage the operators to spend time down on CW and I understand from a recent email there may be DX spot postings online. "We hope to have live satellite internet to the Arctic Circle. We have hams that will be bringing their wireless networks and antennas to set up a satellite internet sponsorship. It is all an experiment so whether it works will be another issue, but we are hoping to be on the web. ~KL7SP~ ARRL AK 2008 Convention Co-Chair

Details of the event are in an article available at
http://www.AL7FS.us/W1AW-KL7.doc
and at http://www.akhamfest.com/arcticcirclespecial.php

The fun starts on July 25th 2008 at 4:00PM Alaska Arctic Circle Time. (or 00:00UTC on July 26th, 2008) and will close on August 10th 2008 at 4:00PM Arctic Circle Time (or 24:00UTC on Aug 10th).

Hi Stephen!

Converting Vpp to Vrms (or rather Veffective = the equivalent DC voltage) for sine waves is done like this:

Veffective = Vpp/(2*sqrt(2)) or approx. Vpp/2.8.

The term 2*sqrt(2) instead of only sqrt(2) is due to the fact that there is both a positve and a negative halfwave over the sine period that drives current (indeed of opposite directions but still generating power or heath) trough the dummy.

So power is calcutated as follows:

P = Veffective^2/Rdummy = (Vpp/(2*sqrt(2)))^2/50 [W]

IMHO the power calculations are correct.

Gang:

I am still trying to post the story of our FD 2008 for the Knightlites.

This is my third attempt.

Here we go again.

* * * * *

Well, this had to be one of the nicest FD events we had on a long trip. It was nice for quite a while and then it had it's low points. I think it should be aptly named a "Lil Ole Mullet Blow to Balsam."

We arrived in due fashion a day early at the site of Black Balsam Ridge and Sam's Knob. Sir Paul/AA4XX and Sir Chris/KD4PBS arrived from their trip up by way of some stops and scenic distractions as described by Paul in his email to the group.

Sir Joe/WA4GIR and I (JP/AB4PP) rode up on the same route and then took the scenic Blue Ridge parkway to the forestry road (816) that leads up to the parking area where we disembarked. This year I can say that when we arrived we did it in a fashion that was perfect. We took our time and got there just in time for a gully washer. The view up there in the evening is awesome. You can see a long way from just the low area where we parked. We waited it out and then after the storm passed we made our way out to the meadow and set up camp. Since Joe thought he had never been there before he was ready for a long hike and found that we only had to walk a short .6 miles to the site on somewhat flat land. I took my GPS that my kids gave me for Christmas and learned how to finally use it for marking the waypoints and reading them out from the destination. The good part was that I also found out during the weekend that the GPS actually does show a true representation of the altitude. I will explain that later. Also, Joe remembered later on that he had in fact been up there hiking years ago. So he was not new to the area either. And there is little change, I am sure, over all those years.

After we set up in the meadow on the Knob the weather changed drastically on Friday night. It went from cool and nasty to cold, windy, wet and wild. We had thunder and lightning mostly all night and it made it a no go for operating on the radio. We had put up two of our antennas and that was so that we could test out the gear on Friday night. We hit the tents and went to bed early. Sleep was not in the picture though, as the weather got worse during the night and progressively got more windy. The constant flapping of the tent flaps was enough to drive anyone crazy. Now, remember that Joe and I had set up down lower than Paul and Chris too. They were set up on top of the Ridge, and it is several hundred feet higher than where we were set up. Those of you who saw the pictures that Paul sent can see that our tents were down on the summit. We were set up on the summit near Sam's Knob. We were right on the Art Loeb trail. Well, not exactly on it, but about 50 yards off the trail in the high grass. Oh, that is another thing. The grass was not quite as high as I remembered it from the past couple of years and that was probably due to the fact that the wind blew most of it down on it's side when we arrived. It did actually stand up during the

day on Saturday and Sunday.

Saturday, sometime about 6:05 am the weather broke and we got daylight coming in as was called for on the computer (my Garmin Legend GPS). As the sun rose the weather changed and it got progressively nicer. By 8 am we had pleasant weather again. We made a jaunt to the parking lot to cook some breakfast. It was easier to go to the parking lot and do it than sit out there on the summit and do it. An added thing to going to the parking lot was that there was a constant flow of tourists from all over the world coming through the parking lot while we were cooking. It is a real hoot to see the floor show as the tourists come up in groups to go on hiking trails. They were carrying and wearing the brand new boots, hiking sticks, the lensatic compasses and all the other new fiberglass hiking sticks. We talked to some and they wanted to know about our fishing poles in the meadow. We explained about the emergency preparedness drill called Field Day. Some were very interested in the use of the radios with only battery power. A few came by the site and saw the gear and others told us they just viewed it from the trail.

Our meals and planning was much better this time for me. I did not take quite as much as I usually do and as an end result I was happy with myself for this accomplishment. I even planned out a more nutritious diet for myself this time. I carried a lot of dried fruits, berries and the like and they went very well with the oatmeal with cinnamon and apples. As for the other meals I had tuna and other items in dehydrated bags. Now, the real accomplishment was watching Joe prepare his meals. He had not done this hiking and camping in a long time. He is in a lot better physical shape than I am and he enjoyed the short jaunt to the site. He runs every day and was not the least winded from our hikes in and out. He had gone to REI and gotten some really good dehydrated meals. I went to the DICKS near the house. They have discontinued their line of dehydrated foods. I went the night before leaving to take off up to the mountain and it was too late to drive to the other side of town to get some of those. I will have to do better planning there for next year. When I got home I found out that they have an Outdoor Provision Company about 5 minutes from the house in another part of Raleigh. Unfortunately I did not know that night. Luckily my son had just come home from Afghanistan and he gave me some of the extra MRE’s he had in his RUCK and I had several meals there. I just took those with me. They are 2500 calorie meals and are very good. Water was plentiful for us. We had more than enough and that was good. I took a 3 gallon jug and we washed dishes and kept clean with that in the vehicle. Thank God for baby wipes too. I took some of those and they are nice when you get sweaty and feel nasty. I had been sending those to the guys overseas for the last year and a half and now I know why they like them so much. And those nutrition bars are a life saver too. Dried fruits are awesome to have in the evening for snacks and just to give you a boost. When we hiked up to the top of the Ridge on Saturday it was nice to reach in my pocket and get some trail mix and some dried fruit to give my body some nourishment. I have learned over the years to carry some of those in zip locks to save draining my body completely of nourishment, especially when I am moving around from one place to another and leave the gear in the other place.

Saturday morning was also a time to go find a place to access the use of the cell phones to call home and check in with them. We had to drive down the mountain 5 miles to a lookout to find a decent signal. One thing we learned while doing this was that Joe, who was driving, should not look at the phone and watch for a decent signal while riding the brakes on the van. When we finally stopped at the overlook we were headed to, we had smoke pummeling out of the wheel wells and it was a site to see. We did not do any damage and just took a rest while the brakes cooled off. We did finally get through on the phones too. It would seem that at 6,214 feet with an unrestricted view you could hit a cell tower; but, that was not

the case. You still had to drive to get within a footprint of a cell tower for service. Another lesson learned about communications. Don't always expect the obvious to be true. It was not for us. Even Paul and Chris said they could not get a signal from the top of the Ridge at the high height of 6,214 feet. I tried with my phone and could not either. Strange as it may, we could see Tennessee, Georgia, South Carolina and all around us was North Carolina. However, we could not get the cell phones to work.

After making our calls Joe and I hiked up to the top of Black Balsam Ridge from the lower road. The elevation at the bottom is 5,700 feet. We hiked the Art Loeb trail up the mountain and crossed the new Mountain to the Sea Trail that is being built. It starts up there in the Western part of NC and goes all the way to Cape Hatteras and goes right through Durham and Raleigh. It showed that if we really needed to we could take a long walk home. We hiked up to 6,214 and it took only 25 minutes. Actually, it was a .66 mile trek up the mountain and it was a change in elevation of only the 514 feet. At the top we met and greeted Sirs Paul and Chris. They had their equipment set up again for 6, 2 and 440. They also had stuff taken down during the night from the storms. It blew a lot harder up there on the top than it did down where we were I am sure. From the top of the ridge you can see Georgia, SC and Tennessee. The view was unrestricted when we were up there and the smog or layer of mist was minimal. You could even see the cloud formations in the valleys from up there. We stayed a while, took some group photos and then we headed back down the mountain together and had a brunch break and chatted about our mutual experiences and our plans for the rest of the FD effort. While we were up there we could see the weather coming our way from the distance. It was very nice while we were climbing up, for the visit, and the climb down the mountain. When we got to the parking lot to head out to the summit though that all changed later. The weather came in with a fury again.

Well, little did we know we were in for more storms and higher wind gusts than the night before. In the early part of the evening we were just trying to get on the air and there was a lot of static in the air. The radio was picking up some signals and we were trying to make some contacts. Without notice I found that the static was higher than I would have expected. I went to touch my paddles and got zapped from a discharge and then looked out the windows of the tent and saw a large storm coming up the valley at us. I yelled to Joe in his tent and he said "wait" several times. He was trying to make another contact. Then I went over and told him as the rain started to come down with a fury. It was big drops, and the wind picked up to a howling fury. He had disconnected as he said he heard this "tick…tick…tick" in his head phones and when he touch his key he also got a little discharge. We decided to unplug everything and wait it out……..

Several hours later we were still sitting there trying to make a few contacts at a time and I sat with Joe in his tent. My Sierra would not tune up for some reason and for fear I had fried it in the storm I did not use it again. Water was getting deeper around the tent, both my vertical (Black widow vertical for 40-10) and the 80-10 meter doublet up on the DK9SQ mast were down on the ground. I had guyed both poles low and the taller one higher up on the mast. In the winds they both came down. So I was literally off the air at my site. I later found out when I got home that the wires where I had soldered the connectors on the antenna had split and come loose. With all the rain and the bad weather I could not get it into my tent and use the little gas fired soldering unit I had for just such an emergency. I learned a vauluable lesson from that one. I keep a diary from every trip I make and that one definitely went into the log. A valuable lesson. There is just so much you can do with the gear when you set up in the open like we did.

We waited for a lull in the weather and made a trip to the vehicle and had some dinner and relaxed for a while. During that time we had a couple more storms roll through and it was beautiful to see them coming; but, when it got to us it was not nice. The lightning display and the thunder were something else. We also had the howling winds again. While in the parking lot we did get to meet some very unusual people. One of them visited both the campsites and he was a wealth of knowledge on the trails and the time people stayed there. As I found out later he lives up there and around the trails the whole season while the parkway is open. Then he moves back down to either his home in SC or he has another place he goes to near Brevard. Evidently Chris and this fellow grew up in the same area and went to the same schools too. They were of no relation and I could easily understand that from knowing Chris as long as I have. There is very little the two have in common.

We went back to the site and made a few more contacts until the lightning started back up and the howling winds started back. We quit for the night and tried to go to sleep. It was a futile effort at the least. It was hard to sleep with all the noise. I made several attempts during the night to get on the radio with no good results. If I had only known that there was a loose wire out there on the antenna I would have overcome that. But with the weather the way it was early on it was hard to get outside the tent and do any repairs. Later on during the night I made one venture outside the tent and it was foggy and it seemed like we were in a cloud again like we had been on an earlier visit to the same site. That was a story we will never forget. This time I had a LED light on my tent, blinking every two to three seconds and left it on while I was away from the tent. It sure did make it easy to find my way back to the tent too.

Sunday morning when I woke up it was a lot quieter. Not real quiet, there were still the remnants of the storms around. We decided to pack up and start our hike out. Paul and Chris had done the same thing. Their camp was dismantled and they came down the mountain as we came out. We all left out at about the same time and headed home. Another FD with the Knightlites was in the books. The contacts we made while we were there were not many; but, they were choice and will never be forgotten. For those of you we did make contact with, thanks for being so patient and good listeners for us.

We did not see any bears, nor did we hear about any. One fellow said that they did see one years ago but not lately. Even one of the park rangers I spoke with at an overlook said they did not see them very often up there. They seem to shy away from the people on the parkway.

We did hear about a snake, from more than one individual, and I am sure they are up there. We did not see signs of them, nor did we see any.

On the way home we did get a little off the beaten path too. Joe and I were talking, reminiscing about the wonderful time we had, and did not notice we took a wrong turn until we saw the “Welcome to SC” sign in Spartanburg. We turned around and made it back to where we started from on the interstate and then went home. Needless to say we added a lot of time to our journey home; but, we were enjoying the trip so much and knowing that we were headed home we did not fuss about it. We were dry, fed and safe. I can definitely say now that with all the trips I have been on for the past 14 years or so with the Knightlites, that I have only seen two of them with fair weather. The rest have all been stories that related everything from near hurricane weather on the Core Banks, tornadoes on Falls Lake during one of the ARCI contests to the awesome storms in the mountains on the trips we have made to Max Patch and Black Balsam.

All in all, though, we had a wonderful time. We learned a lot and will just have some things to plan for on the next outing.

3343. 2008 Flight of the Bumblebees - July 27

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-07-17 13:26:25 UTC
From: scott mcmullen
Topic: 3343 Message: 3343

The 2008 running of the Adventure Radio Society's 'Flight of the Bumblebees' is approaching on July 27. So far, 143 intrepid QRP operators have signed up to hike, bicycle, or paddle to an operating position and participate in the event as Bumblebee stations.

Participation from home stations is also welcome and encouraged.

Group operation is welcome in the Flight of the Bumblebees. You may operate under a single call and report a single score, or under multiple calls and report multiple scores. In any event, you are limited to operating a single transmitter at a time.

Maximum power is five watts. We operate CW on 40, 20, 15 and 10 meters, on the standard QRP frequencies. Each contact will receive one point. The same station can be worked on different bands for additional QSO points and multipliers.

The rules in full, and details about soliciting a bee number, are available at:

http://arsqrp.pbwiki.com/Flight+of+the+Bumblebees

Hope to hear you on the air during the 2008 ARS QRP FoBB

73

3344. Firmware Version Command

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-07-18 17:08:10 UTC
From: kr5l
Topic: 3344 Message: 3344

Hi,

I finally got around to building my 3B. I have had many, many QSOs with it and it is a pleasure to use. I have a couple of anomalies:

1. The firmware version command doesn't work with my unit. When I hold the menu button and then plug in the power connector.... the unit just comes up displaying and announcing the band module.... as if the Menu key wasn't pressed during power up. I have tried this several time with no success. (Not a big deal -- but it doesn't work) \

2. Placing my 3B in 'Stealth' mode (using the push buttons for paddles or straight key) works as advertised until I try to go back to external paddle/straight key operation. The Tune Dwn button generates dots and the Up button generates dahs.... not imabic.... squeezing both paddles results in a string of dahs... not alternating. Weird. Also, any announciation such as Freq, Menu fucntions (S,M,etc) are sent over the air!!! I had to try every trick in the book to retrieve my 3B from the "Twilight Zone". Again, when in Stealth Mode, the rig behaves okay, it just acts strange when I try to exit the Stealth Mode and go back to normal operation.

Does anybody have any suggestions or ideas as to what is going on here?? Neither problem effects my day to day operation as I would rarely use the Stealth Mode and of course the Version Feature would be useful if there was a firmware upgrade. I would be nice to have all features working properly.

Thanks in advance for your help. 72's

Jerry Henshaw KR5L

Jerry,

Congrats on finishing your 3b!

I haven't seen the version not annunciated so this is a first. Can you try this: Pull the power plug. Hold the menu and split buttons down for about 5 seconds (this discharges the caps so the boot process won't think it's an overcurrent condition, which would bypass the version annunciation). Then, just holding the menu button down apply power.

For the alternative paddle mode, we'll need a little more details as to how you got in and how you tried to get out. I have not tested or looked at what Steve did in his version for this, but since he's out for a few weeks I'll try to help, but need much more detailed information.

3346. W1MT firmware Memory Functions

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-07-19 01:02:31 UTC
From: kc7fys
Topic: 3346 Message: 3346

Hello Mike and others listening in,
I am having a little trouble utilizing the memory functions in your version of the firware. Pressing V+M in rapid succession gives me a B. Pressing them together, of course, gives me the F function.

Could you for posterity outline how to:

Record each of the three memories
Save them
Check what is in them
Erase one of them and re-record
Play them back

...for the dufuses in the group, me being Chief among them.
Thanks, and I am really enjoying your firmware's SCAN function.

I have a suggestion, and let me know if this is reasonable. I can't tell when it is scanning UP the band, or scanning DOWN the band. Would it be reasonable to have a different letter annunciated at each end of the scan range... I can't think of a suitable one that wouldn't possibly be mistaken for other indications. ST and SB? (seems too long to be practical...)
Just a suggestion.
Best 73,
Jonathan Haynes 7J1AWL/KC7FYS

Mike,

Thanks for the quick response, I tried your suggestion of holding MENU and SPLIT to discharge the caps and then I tried holding Menu and power up .... still no cigar ... go figure.

The Stealth Mode is another story. I was finally able to get the 3B back into normal mode by enabling and exiting the mode several times before I was back to normal operation. I haven't tried going into Stealth Mode again as I wasn't sure I could ever get the CPU back from never-never land again. There is something flaky going on within my CPU with the version and stealth mode issues. I might just have a corrupted software download. As I said, everything else works just fine. Thanks again for your help and I appreciated any additional thoughts that you may have concerning these issues.

All The Best,

Jerry, KR5L

Playing memory:
Probably too quick on clicking the V then the M to get memory 1 to play. Try playing with the timing... I just check it on mine and if I have the clicks too close together then it just does the vfo switch (B or A). It's all in the timing. :)

Storing memory:
When you enter M mode you have to store all three memories during the same session. You can not edit just one. (This area needs work :)) Start entering the first memory then when done with the first memory hold the dah paddle down for seven dahs. Then enter the second memory and enter the 7 dahs again. Now enter the last memory. If you goof one of the memories you can click the tune down key to backup for the last 7dah (or beginning) marker. This will allow you to try the last memory again. I find this helpful cause I generally don't get all three right and it gives me a way to fix the problem rather than have to enter them all again. When done click the menu button and you will hear what you entered. Should sound something like "memory1" 7dahs "memory2" 7 dahs "memory3". Note, you don't have to enter all 3 memories. 1 or 2 is fine. Ha, you can even enter more than 3 memories but currently only the first three are playable.

Scanning:
It never scans down. Only and always up. You will hear an "S" when it loops from the highest scan freq back to the lowest scan freq.

Hope this helps,
Mike

3349. ATS-3b finished - not working :-(

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-07-19 15:24:14 UTC
From: Heinz
Topic: 3349 Message: 3349

Dear all,

I have finished completion of my ATS-3b, but it is not working. It is one of the recent kits from KD1JV shipped in late June 2008.

I am at the stage where all components except L3 are fitted to the board (page 23 of the manual). When I connect a 9V battery I see "8" on the LED display (for a second or so) and also hear "8" in the phones. Then I hear a continous sine tone in the headphones. The frequency is not influenced when adjusting CT1 (BFO trimmer cap).

I can trace the signal with a scope and find it on pin 7 of U3 (Audio Amp) with 0.7Vpp It is not on pins 5 or 6 (?!?). I can further find it on pin 1 of U3 (0.6Vpp; slightly distorted) and on the 5V line with about 0.1Vpp.

Voltages according to table on page 24 are OK with the following exceptions: pin 1 of U4 (Analog SPDT switch) is 2.48V (expected 2.2V) and pin 4 is 0V (expected 2.2V).

I have resolded all pins of U4 with no effect.

I can key my paddle and hear the proper side tone in the phones (The controller definetly works!). In between caracters I still can hear the annoying sine tone.

Did I fry U4? Any ideas what I can check out next?

Hi Heinz,

Got my ATS-3B kit 10 days ago. I did the same tests today, and
everything worked fine. Will proceed tomorrow with the ref osc
calibration.

Since U3 is powered by 5V and you measure a 100mV oscillation on 5V,
it's not surprising this appears on the output of U3. I would check
why the 5V supply is oscillating: U9, C25, polarity of C59.
What's your supply current during this test @ 9V DC IN ? Mine is
around 40mA after seeing/hearing the "8".

73, Markus HB9BRJ / AE6MG

Hi Markus,

Congrats on your ATS-3b and thanks for your reply.

My supply current is 80mA @ 9V DC. I have checked the voltage regulator U9 and surounding C's, nothing found.

I have added another 220µF in parallel to C59. This lowers the frequency of the tone slightly and knocks down the signal to 5mVpp at the head phones (but still heared at an offensive level).

If it would not be SMD I could easily lift the 5V supply from U6 and power from a seperate supply to circle in on the source of the signal. I will try this next...

73 Heinz, OE5EEP

This should be ...down to 50mVpp...

Jerry, you need to have a straight key in the paddles socket to get the firmware version, or just insert a mono plug. This is a known problem with the firmware. If you plan to run 80m you might want to upgrade the original firmware if necessary to V3 which is in the files section. This fixes an 80m Direct Frequency Entry problem. It also has a fix for the XIT function.

You can hold your DOT paddle closed while holding the Menu button
down on power up. This also works!

Something that took me a while to figure out with Mike's version:
You can't roll from the V to the M (or U or D). You must release
the V very briefly before pressing the M. At one point I had modified
Mike's code to allow button roll-over, but it was incompatible with
some other new functions, so I just learned not to roll from the V
to the M by using only one finger rather than two.

That's right. Thanks for kicking my memory Jim.

You need to hold the Dah paddle down and the menu button at the same time if you want to hear the version on Steve's firmware. (His original version 1 and newer version 3 both do this.) This effectively puts the rig in straight key mode after bootup is done. (Course with a two conductor straight key plug the dah paddle is held for you).

From: Larry Makoski W2LJ
Topic: 3358 Message: 3358

This Sunday night s the July Run For the Bacon, which is a friendly two hour QRP Sprint sponsored by the Flying Pigs QRP Amateur Radio Club International.

It's looking like Sunday is going to be a hot one across a lot of the country. Maybe the hot weather will induce the ionosphere to be hot and give us great conditions for the Sprint! Well, we can hope, anyway!

For the details and the Autolog, please visit :

http://www.gentzow.com/fpqrp/fpqrprun.php

See you there! And by the way, think of this as a "warm up" for the Flight of the Bumblebees to be held next Sunday!

3359. typo in ATS-3B manual?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-07-20 07:51:23 UTC
From: Markus
Topic: 3359 Message: 3359

Hi all,

On page 23, the manual (V3) says:

"Connect a voltmeter between ground and the Drain of Q4, the PA keying transistor (Large metal tab is Drain). Send a string of Dahs and watch the voltmeter. The voltage reading should go to near the DC supply input voltage. It should then slowly decay to zero when you stop sending."

Q4 does not have a large metal tab, and according to the schematics it's Q6 which keys the DC power line going to the PA.

Therefore I assume that Q4 in the text quoted above should read Q6.

I was afraid my ATS-3B did not work, but on the drain of Q6 I observed the expected behaviour when operating the paddle.

Correct. The 3B-incorrect text carried over from the ATS-3A manual;
Q4 in the 3A is Q6 in the 3B.

From: Markus
Topic: 3361 Message: 3361

Hi all,

Since the weatherman announced a rainy Sunday (which turned out to be totally wrong), I took the time to check and align my ATS-3B.

Most alignments went really smooth. The reference oscillator was very close to its nominal frequency (guess less than 20Hz). Also the LO frequency trim required only a single click.

On 15m (the only bad filter I have built so far) I measured 2W at 9V and 3.5W at 12V. So far I was not successful to bring the power up to the values mentioned in the manual. Seems to be really tricky on 15m.

RX MDS is below 0.2uV, but the TX harmonics are not yet where they should be. Think this goes together with output power and needs more tweaking.

Will build the 80m band filter next. Hopefully that one will be easier to align.

Heinz,

It does sound like U4 is or something around it might be the culprit. Here are a few things to look at:

The mute pin (pin 29 of the MPU) controls the digital switch (U6). Make sure that the signal from the MPU is making it to the switch.

The ripple on the 5V line should not be there (assuming the source is not the power supply). So check every device that is fed by 5V and make sure there are no solder bridges around the 5V input to those devices. Finding this one should take care of the high current draw as well.U3 may be a good first place to double check as well as the DDS chip.

A good magnifying device will come in very handy during this process.

Good luck,

Run for the Bacon
Sunday July 20, 2008
6:00 pm - 8:00 pm
(This event repeats every month on the third Sunday.)
Location: Your shack or anywhere

Notes:
This Sunday evening, the Flying Pigs Amateur Radio Club International will be holding its monthly Run For The Bacon. This is a friendly, two hour QRP CW Sprint, which is open to ALL radio amateurs, will last from 9:00 - 11:00PM EDT (0200-0400 UTC Monday).

You may work stations once per band on 160, 80, 40, 20, 15 or 10 Meters. Suggested starting frequencies are 1.812, 3.562, 7.044, 14.062, 21.062, and 28.062 MHz.

The exchange is RST, S/P/C (State, Province, Country) and Flying Pigs membership number. If you're not a member of the Flying Pigs, and would like to be; then please cli

3367. ATS-3b variable bandwidth filter experiments and other ideas

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-07-21 01:13:10 UTC
From: Vojtěch Bubník
Topic: 3367 Message: 3367

Hi gang.

I finally found time to experiment with variable bandwidth crystal filters. I copied the idea from Elecraft K1, K2 and KX1 transceivers. I replaced three shunt capacitors in crystal filter of Steve’s ATS-3b prototype with KB313 varactors. As I remember from crystal ladder filter theory, the filter is reasonably flat only if it is loaded with proper impedance for which it was designed. To make the filter wider, one decreases shunt capacities and increases matching impedance. The Elecraft variable bandwidth solution is clearly compromise having constant loading impedance, but varying shunt capacitors.

Elecraft is using 1SV149 silicon epitaxial (whatever it means) varactors in K1, K2 and KX1 transceivers. The varactor is special by having very high capacitance ratio C1V/C8V = 15(Min.) and Q=200 with C1V=340pF and C8V=20pF. For ATS-3b one would ideally need a varactor with C1V=150pF and C5V=20pF, but I know of no such device. There are varactors with C1V around 150pF, but these have the lower capacity too high or need too high voltage. So one will not use the full range of 1SV149 capacity for variable filter bandwidth.

I found KB313, varactor similar to 1SV149 made in OK land in cold war era. The shop stocks triplets of paired varactors for about $.50, good deal indeed. Dan’s small parts stocks similar high capacitance ratio varactors. I measured following capacities on KB313 varactors:

C0V=770pF
C1V=470pF
C3V=143pF
C8.8V=28pF

The last voltage 8.8V is not magical value. It is the voltage of a battery that I used to derive varactor reverse voltage.

I measured ATS-3b passband with noise generator and DL4YHF Spectrum Lab at earphone output and on AVC chip output. The earphone amplifier in ATS-3b is wired as Sallen-Key 600Hz band pass filter, so it has distinctive peak, which is roughly independent of the crystal filter bandwidth. I see two secondary peaks on the spectrogram, which I cannot explain. Anyone has an idea?

Here is the spectrum lab software:
http://dl4yhf.ssl7.com/spectra1.html

Here are the screenshots I made with Spectrum Lab with various varactor voltages. There is also a photo of the testing configuration. I am using 9V battery and 10k pot to get the variable varactor voltage. The board on the picture is actually a fixture for measuring varactors on a homebrew LC meter.
http://www.kufr.cz/~ok1iak/temp/ATS3b-filter/

I will test it on the air to receive SSB and AM. The variable bandwidth seems to me a useful feature. Even with the Sallen-Key CW audio peak filter the higher bandwidth of

crystal filter will make searching for the stations easier. Anyway, I plan to do some tinkering with Steve’s prototype and pour some more silicon into it. I have two Microchip I2C D/A converters and mechanical rotary encoder on my table. With various priorities, these are my plans for the future:

- Liberate most of the MSP430 display pins. The plan is to use 74HC164 shift register, feed it with two pins (clock and data) and connect display to its parallel output. This will free 7 CPU pins for other experiments, two of the freed pins may be used for A/D, like power meter, PSW meter or PSK31 envelope shape feedback.
- Perfect PSK31 envelope. Will consume one of the two I2C D/A converters.
- Variable crystal filter bandwidth. May consume the other I2C D/A converter. Maybe a simpler solution will work having two or three fixed bandwidths switched either with mechanical slide switch or by CPU.
- Reconfigure the earphone amplifier as low pass for SSB reception. Extend firmware to allow for both USB and LSB on all bands. This may not be possible for all bands because of limited DDS coverage:
3.5MHz is shifted to 4.9MHz IF by adding 1.4MHz DDS leading to USB detection. By subtracting 8.4MHz, one will get LSB image in the same IF filter.
7MHz is shifted to 4.9MHz IF by subtracting 2.1MHz DDS leading to LSB detection. By subtracting 11.9MHz one will get USB image in the same IF filter.
DDS maximum frequency limits this trick to 20m.
- If the earphone amplifier gets rewired as low pass, then add a new Sallen-Key CW 600Hz band pass filter and add a bypass circuit to switch it off when using wide crystal filter settings for SSB or AM RX.
- Tuning with mechanical encoder. Make tuning step smaller and increase tuning steps if one rotates the knob fast. Detentless encoders are hard to get, but fortunately it is usually easy to remove the detent. Will free two buttons for other purposes like bandwidth selection or RX mode selection.
- Programmable sidetone level. Probably only software change is needed. One may control amplitude by pulse width modulation of the sidetone pin.

I will implement these features when I have time and mind for it. It will be fun for sure. On the bottom side of the ATS-3b PCB there is plenty of solid ground plane to do some SMD dead bug creation with magnet wire and kapton tape. That will train my patience and steady hand. Hope I will spark off some other experimentators.

As an English teacher, I have just gotten used to the creative spelling of hams in general. It's a realm of engineering-types who generally share the spelling habits of artists and musicians. Their creative energies lie elsewhere. I know little about RF theory, but I can find spelling errors in anything. With me, it's a savant behavior. The case of hams drives home my idea that intelligence and creativity and spelling ability are not related.

Markus,

Congratulations on getting your rig running!

The filter modules for the various bands require careful adjustment in order to get optimum performance. Adjusting the turns and the capacitors will affect power output, current drain, efficiency, harmonic output, and peak RF drain voltage. The "stock" values you start with may not be a very good compromise.

The situation is complicated by the PA overcurrent sensor, which may trip on some bands if you adjust for power output close to 5W.

I posted papers on these adjustments in the FILES section on this site. The details will test your patience, but I believe the results are worth the time spent. It is possible to get nice performance on all six bands.

There is a large amount of information concerning the filter modules posted over the past several months here. Please use the SEARCH feature to find various messages dealing with adjusting the modules.

Good luck with tuning up your filter modules!

You could also have a short circuit under some SMD component or some bad soldering that you do not see with the microscope. I check the contacts and shorts always with a multimeter. I wonder why that is not part of the standard check procedure - is there any issue of possible damage to the semiconductors? I remember that there used to be a recommendation to use a series resistor with the multimeter to proctect GaAs FETs when measuring them. See for example the ARRL UHF/Microwave Projects Manual. Anyway you need to take care of ESD during the construction and testing, otherwise you may get bizzare problems later and end up having 'almost' working radio.

I just finished building my ATS-3B a few days ago, and had the exact same problem. The problem was a bad solder connection on C17 (470 pf) next to R5. This caused U3a to oscillate. A touch of the iron, and the rig has worked since. This caused the ripple on the 5 V rail also. Maybe this is your problem also.

Good luck,
Jim, w5jaw

Topic: 3372 Message: 3372

I finished my build a couple of days ago, and am having lots of fun with my ATS-3B. I am new to this group, so forgive me if this has been covered in the past.

When I check version number on power up I get "V34". I see when scanning back on this forum a ways that W1MT has issued Version 5. Is my version really 3.4 or something like that? I just received this kit a couple of weeks ago.

The reason I ask is that everything seems to be working fine, but I find the iambic keying very difficult to handle, at any speed. I am an experience QRQ operator, using full "squeeze" iambic mode "B". There appears to be no hold-off timing, so am getting too many errors. Saw some mention somewhere that some keying changes had been made in later versions.

Thanks for any info on this.

You have Steve's version 3 and probably have the 40 meter board plugged in. Hence "V34" (version 3 band 4).

Same problem here. W1MT's v8 firmware allows to change between keyer
modes A and B. But you need extra hardware to do the programming.

A very nice - although not cheap - alternative is the "Code Cube" by
http://www.palm-radio.de/ that clips to their "Mini Paddle" which I
plan to use when operating /p.

First priority here however are the band modules. Different authors
have published proposals for improvement.

From: spitleaf
Topic: 3375 Message: 3375

Hello group,

Got started at my kit today and when I was going to mount the 11 471
0603 sized resistors (blue painted package) they were replaced by 511.
I guess that's 510 ohms? What I'm wondering is, is this just a mix up
when kitted or are they infact replaced?

Thanks,
Alexander

3376. "E" on XMIT... How do I determine if I blew my finals?

Yahoo group: AT_Sprint (2002 — 2008)

Good morning, it is a humid and sweltering day in JA1. Promises to be even hotter as the sun rises.
I have been mired in antenna pruning, so have not been paying attention--and might have blown my main output transistors.
With the 80, 40, and 20 meter modules in place I get E on transmit with 12V supply, but get a wee 80mW with 7.5V supply from a partially spent 9V battery. This is into a 50ohm Norcal Dummy load and into a resonant (1.6SWR) antenna that was working just fine the other day.
What steps should I follow to determine what's going on? Oddly, I get 6Watts out with the 15 meter module in place.
That doesn't make a bit of sense to me.
This is a working ATS3B that has been tested and tweaked on all modules without problems.
Replacing the finals from Tokyo will be no problem (I should have kept spares on hand, actually)--but I need to determine that's actually the problem, and I'm not totally on the wrong track.
Receive is normal, of course.

Jonathan,

If you get 6W out on 15M, your finals are OK. 6W is too much, and I'm skeptical , but you're getting solid output, so the final mosfets are not burned out.

I have never blown my finals, but what I think happens is that one of them gets too hot, and then it shorts out. The rig won't transmit after that. because the current sensor would trip. It's also possible for the drain protection zener to short out if the load impedance is not matched right, but this also would make the transmitter short and trip the current sensor.

An SWR of 1.6 may be unacceptable to this rig. Depending on the magnitude and phase of the standing waves, the current drain may exceed the design limit, and then the current sensor will reset the micro and show an E. I think that this rig almost always needs a tuner when being used with an antenna, like it or not. Numerous tests on my bench convince me that the current drain moves around quite a bit, even with a moderate SWR of 1.3 or 1.4. If the current drain goes up much, like 10 or 20%, the sensor trips. This is especially true with 12 volts in.

I would not expect your symptoms on an accurate 50 ohm dummy load. That doesn't make sense, unless you're running on 12V or more, which could trip the current sensor. I had to alter the threshold on my current sensor up about 10% to give the rig a little margin for tuning. I think this is required if you want to run 12V in and 5W out.

I found that the current drain on my rig is highest on 15M, so it also doesn't make sense that your rig would work at full power on 15M and not on other bands.

To see if the current sensor is tripping, look at the collector of U5, MMBT2222A. If this goes low, like a volt or less, it resets the microcontroller on pin 7.

The current detector U12's output is partially controlled by resistor R47, originally 680 ohms. I put 5.6K in parallel with R47 - this lowers the output of U12 going into the base of Q5, allowing a higher current to flow through the finals before current trip occurs. I always tune with a resistive bridge (Dan Tayloe LED bridge device,

like the BLT uses) and a 6.7 ohm resistor in series with the 12V supply, and I don't get nuisance trips when tuning on any band, regardless of the mismatch. Only when the load is matched do I switch to "operate" and short out the series resistor in the battery pack.

Note that U12, the ZXCT1008 current detector, is not a threshold, comparator, or digital type device. It is a straight linear amplifier operating on the high side of the supply. The output at pin 3 is approximately proportional to the current through the sense resistor R48 (0.1 ohms).

This is why you can adjust the trip point by changing R47. You also could increase the trip current by reducing R48, the sense resistor. Putting 1 ohm in parallel with R48 (0.1 ohm) would increase the trip current by about 10%. Likewise, increasing R49 would also increase the trip current of the circuit.

I recommend you increase your trip current slightly if you plan to run with 12V and expect to get 5W out. If you set it too high, you risk blowing your finals.

Let's hope none of us is trying to run this precision radio on something like a wall-wart. I can't think of a worse way to screw the radio up and to wreck the performance. Many of these crude power supplies have an output MUCH higher than the nominal voltage stated on the cube. Using such a device may lead to permanent damage, and it would make it very difficult to adjust the RF modules correctly.

Only a regulated supply or low-resistance battery should be used for operating. Only a regulated supply should be used for adjustments and measurements.

We see a lot of comments here about running on "half-dead 9V batteries", etc. Steve Weber deserves a gold star for making a rig that will run on such a battery and deliver a legal signal...but using a crummy battery to run this little jewel makes no sense at all! That's like running a sports car on turpentine! This rig will do great stuff is you give it a decent battery. Try three lithium ion/polymer cells, 8-10 NiMH cells, a 12V battery with a silicon diode in series - you're going to be happy!

I am using a battery from a computer UPS. The output is about
11.8-12.1. Today's behavior represents a major change from past
performance of this radio. Let me check that I'm right about that
weird 15M 5watts out--that part doesn't make sense.

I'll check that U5 that you mentioned.

The Norcal SMT 50-ohm dummy load trips the E. That's what I can't
figure out. I'll keep tweaking around--usually these issues are
something I am overlooking. Usually something obvious.

Back story--I am gearing up for a family trip to Vietnam, and have
tentatively obtained permission to operate mobile CW there. This might
be the first ATS rig in Vietnam, or maybe the first ATS3B. IF I can
get this weirdness ironed out.

Well, I took the board out and sprayed it with a flux cleaner spray
(it wasn't bad anyway, but there was a sort of whitish residue on a
lot of the solder joints on top of the board incidentally). Anyway,
now I can't reproduce the negative results I had last night when I
typed that long description.
I will consider your current limiting mod, however. But for now, hm--I
don't know what was causing my failures last night. I guess I'll have
to wait until it happens again. Who knows.
Thanks for your comments.

Or just use a diode to drop the supply voltage until you get time to take it apart and do the mod.

Was it working fine with the 12V supply? or with lower voltage?

Btw, I only have ever run my ATS rigs at 12V for testing. Just too many nuisance trips. Never in the field. Usually 7.4V or 9.6V with 11.1V max being the max I run it. I've got my trip circuitry stock for now.

I don't know if Steve replaced them in the kit but those resistors are for current limiting. The 510 ohms should work just fine where the 470 ohms were.

Well, for now I am A-OK with 12V, and 9V for tuning up. Something's going on, because tonight I came up with my 40 module in, and was just fine into a 1.4 SWR on 7.030 +\-. HL2 could hear my signal, but couldn't copy it before QSB took him, but I worked up and down JA pretty well--indicating that last night's problem is strangely absent tonight. Not exactly comforting, knowing whatever I was doing wrong last night mysteriously disappeared. Anyway, my finals are not blown.

I do have a question, Harnage-san.
I want to change the annunciation speed, followed your cheatsheet to the menu--got in that mode, then realized I didn't know how to increase or decrease it. Paddles were non-responsive and pressing other buttons put me into different menus. How do I say, increase the annunciation speed? Is there a *set to default* in your firmware, in case I get out into the weeds and can't get things back to normal?
Thanks for your comments, I'm enjoying your firmware.
Jonathan

I changed the annunciation set to mimic Steve's. Set your transmit speed normally. Then in the "P" menu TuneDown will set the annunciation speed equal to the transmit speed. Remember to click menu twice to completely exit P mode.

Jonathan,

I think I used a 1/4W leaded resistor, but you can use whatever is convenient. The power is low, and the value certainly isn't critical.

Based on the information you've given us here, I can't see any reason for the changing behavior of your rig. It would make sense to examine all the solder connections related to Q5 and U12, just to make sure they're solid.

I wouldn't be running my rig at 12V and 5W if I didn't think I could replace the finals easily - they are cheap and easy to get. Also the "B" rig has an overcurrent sensor, and I have polyswitches and/or protection pcb's in all my battery packs - these protect against catastrophic shorts. Cheap insurance...

Good luck on your trip!!

Well, all solder joints appear patent and in order-except for the odd white powdery residue. (I'll take macro photos later.)
The best I can conclude is that my overcurrent sensing has actually _started_ working right for the first time. In the past months I was occasionally getting 13v from 10 fully topped-off ni-mh AAs. That was never an issue and there were no trips. Now, 8 of the same cells (the "orange zone" on my KD1JV voltage indicator-11~11.9v)won't trip and gives me the full gallon.
Not explicable, but my signal's out there, so... (shrugs)
Going to keep extra 2N7000s around, if I can locate them here in JA.

From: Jim Fraser
Topic: 3168 Message: 3390

I have still been looking at this problem on occasion as it is not yet resolved. I requested from Steve, received and replaced the AGC chip, but that did not help. The problem again is that the audio level on receive is very low with an antenna connected.

While poking around I happened to touch the band module with my finger and the receive noise increased a quite a bit (40m). I used an exacto knife as a probe to determine which point in the board is giving me the increase in noise level. The point is any component directly connected to pin 1 of the band module, the input to the RX circuit on the main board. The background noise level is about what I recall from when I first built the rig (this is a recent problem). The effect occurs with all band modules, but is most dramatic on 40m and 80m.

I checked the connections from the band module connector to the main PCB and it looks OK. Tracing back I thought it might be a problem with the QSK circuit not letting the receive signal through. I did some T/R voltage measurements and replaced Q2 and Q1, but the problem persists. The documentation states that on receive Q1 is turned off and Q2 is turned on. This allows Q2 to pass the signal from the TX low pass filter through to the RX's input tuned circuit on the band module. It seems that the signal is not passing through.

I am not sure how to interpret the voltage readings on the three FETs Q1, Q2, Q3 in the QSK circuit. The voltages in RX mode with the 40m band module installed are as follows:

Q1: Gate = 0v, Source = 0v, Drain = 0v -- OFF?
Q2: Gate = 3.5v, Source = 0v, Drain = 0v -- ON?
Q3: Gate = 3.5v, Source = 0, Drain = 0v

Does anyone experienced in FETs see a problem with these values? You may reply offline.

The transmitter does work putting around 4w at 12v (40m).

Pls note: the deadline for getting a bee number is rapidly approaching.

The 2008 running of the Adventure Radio Society's 'Flight of the Bumblebees' is on Sunday, July 27, and runs from 10:00 PDT/11:00 MDT/12:00 CDT/1:00 EDT to 2:00 PDT/3:00 MDT/4:00 CDT/5:00 EDT.

So far, 180 intrepid QRP operators have signed up to hike, bicycle, or paddle to an operating position and participate in the event as Bumblebee stations.

Participation from home stations is also welcome and encouraged.

Group operation is welcome in the Flight of the Bumblebees. You may operate under a single call and report a single score, or under multiple calls and report multiple scores. In any event, you are limited to operating a single transmitter at a time.

Maximum power is five watts. We operate CW on 40, 20, 15 and 10 meters, on the standard QRP frequencies. Each contact will receive one point. The same station can be worked on different bands for additional QSO points and multipliers.

The rules in full, and details about soliciting a bee number, are available at:

http://arsqrp.pbwiki.com/Flight+of+the+Bumblebees

Hope to hear you on the air during the 2008 ARS QRP FoBB

> modes A and B. But you need extra hardware to do the programming.

Corrections:
(1) Also Steve's ATS-3B soft does have iambic modes A and B.
Discovered it when reading the manual in detail.

(2) Reprogramming the microcontroller only requires a cable and
6 resistors, as described elsewhere in this forum.

Sorry for having posted incorrect information.

I'll give the W1MT firmware m008 a try, because I'm still a bit
unhappy with iambic mode B as implemented by Steve. Letters R and F
come out wrong most of the time. Am using Accu keyer and Idiom Press
CMOS Super Keyer since 30 years. Very difficult to adapt to something
different, hi.

From: Markus
Topic: 3394 Message: 3394

Hi all,

Thanks to all who are contributing hardware (Steve), software (Steve and Mike) and useful hints here in this forum.

CW keying issues made me try Mike's firmware M008 dated 18JUN08. The DIY cable with 6 220 ohm resistors worked fine. The programming instructions were easy to follow, except the very last step: After hitting CTRL-D I didn't find any RUN button to click. Because the debugger log said something like "transfer verified" I simply unplugged my ATS-3B but was not sure if it was programmed or not. The version check then confirmed I have successfully uploaded Mike's firmware!

Good news: The CW keyer now works similar to the many "mode B" keyers I'm used to. Thanks Mike!

Next I started to work through the "cheat sheet", thinking the new commands were implemented on top of Steve's. This seems to be the case only partially. Soon I found out that RIT/XIT have been modified to a dual A/B VFO plus normal/split modes. I like it!

When changing the transmit speed I got no result whatsoever until I tried the paddle instead of UP/DOWN as indicated. Either it's a typo on the cheat sheet, or I'm doing something wrong.

To really get familiar with Mike's command set, I am planning to create a "quick reference" table situated somewhere in between the existing cheat sheet and a plain text description. Per function, it will list the user actions required as well as the ATS-3B's LED and acoustic responses.

Before reinventing the wheel, let me ask if somebody out there has done this work already.

Markus,

Glad you like it!!!

Regarding changing speeds, I need to change the cheatsheet to match actions. :)

It's this way because I added subroutines to handle checking for dit's and dah's. You will notice that to change speed, when you are in button paddle mode, the tune down and tune up buttons will change the speed.

My 3B firmware does indeed have improved iambic timing. Several hi-speed ops have told me they like it. Eventually, I will port it to my ATS2,3,3A version.

I have to give thanks to Dave/WA3OFF for his software insight in this area and other areas that are not so apparent. He has been a huge help.

Well, my 3B has it ears back again! Thanks to a tracing tip from Mike (w1mt) I determined that I was losing the antenna signal at capacitor C41. Luckily I had one spare left and decided to replace it.

To my surprise when I heated up one end and applied the solder sucker the whole device disappeared! I opened the sucker to retrieve it and found that tip of one end was missing, the capacitor was cracked. I wonder if this was from a little flexing the board took when fitting it into the Altoids case? It is also pretty close to the band module connector which could flex a little too.

Anyway, the rig is now safely in its enclosure. Made one QSO on 40m with a station near Portland, OR (560 miles) last night who gave me a 479. No luck today on 20m, very poor conditions here. Tonight I worked into Farmington, UT (597 miles) on 40m where I was 559. This is running about 4w out to Hamstick verticals on my second floor balcony with a BLT tuner. I am soon going to try a wire vertical using a 31ft fiberglass pole I have which I hope gives me a better signal.

Thanks to Mike (w1mt) and Tom (k9ac) for their suggestions off line. Conditions permitting, anyone in the Rockies and points West can listen for me on 7030 or 7040 around 0200-0400UTC.

72,

I about to send my check off to KD1JV for an ATS-3B.

Wondering if there is an ATS-3B builder or operator in the St. Louis, MO area available to share experiences, provide guidance, etc.?

All of my scratchbuilt and kit projects have been thru-hole so SMT is scary. It's probably one reason why I have waited so long - and hopefully not too long - to order a kit.

I'm recently retired so now have the time to build and run portable at a more relaxed pace. It's gonna' be fun! <g>

Thanks,

Dave, NF0R

Dave you're going to love your Bee AND you're going to enjoy BUILDING it. SMT construction, you will find, is perhaps the easiest thing that you have tackled lately. This great "mystery" about SMT and the resulting fear is just bunk. Get yourself (if you don't already have) a good SMT soldering station and a good set of binocular magnifiers (visor). Read as much as you can stand about SMT technique (Goggle), practice by un-soldering odd ball components from a junk box pcb like a PC modem board or the like.

Getting to the adequate stage will take you a couple of attempts with the junk board from there it is just like getting to Carnegie Hall practice, practice, practice.

You CAN build it your self and there are a bunch of folks here to provide support should you need it. Download and read the manual a few times to acquaint yourself with the rig while your waiting for it. You will find that the manual is pretty darn good. If you follow the script you will do just fine.

Go for it.

Steve is out of town for a hike according to the webpage so don't get concerned if you don't get an immediate response.

He does repair work for Small Wonders Labs and he fixed my DSW-II. A small gob of solder was in between two of the legs of a 2N7000 transistor. Fixed it just fine.

Only problem I had is I connected it up to a PAC-12 and turned it on. It started to cycle up and went dead. I looked at horror and saw the tap fell off the tuning coil! Man am I depressed. It worked so well into the dummy when I got it back from him.

Waiting for him to come back and see if I can send it back for him to resurrect. My fault.

News!

Thanks very much to KC9LDH, W1IN and WC7S for their comments and encouragement. You are appreciated!

My sense is the ATS-3B is something I just have to build. I've been running portable since 1981 (the old HW-8 and Argonaut 509 days). This will be quite a nice change for the OM on the hardware side.

I also heard words of encouragement from ATS-3B builder N0AL who lives (believe it or not) only about three miles down down the road. I look forward to meeting with Alan and talking radio sooner than later.

It appears the AT Sprint newsgroup is a great amateur radio resource for builders and experimenters. I look forward to contributing in the months ahead.

After building four of the ATS series, I have to say that they are my favorite radio to build. I dread doing through hole soldering anymore, sticking a few parts through, bending the leads, flipping the board over, soldering, only to find one has slipped a bit and is not perfectly flat on the board. Instead, put a dab (tiny!) on the board, slide part in place, tack one side, solder the other and you're done. Well, not quite that easy at first, but it gets easier. I suggest spending $7 and building the Norcal dummy load for practice. Forty resistors to practice your technique and you have a useful QRP tool.

wow, 4 ats3bs.

I have been on the verge of taking the plunge.
whats the chance of someone with this type of experience posting a real straight forward post about the dos and donts of this project??? most difficult procedures and ways to deal with them etc etc.

I would give my neighbors cat for a good resource like that.

Most of us have some basic solder skills. I am in the middle of a bare-bones K2 and hopefully when I get finished, I should be ready for the SMT.

Could you list some of the best recommended sites or prep kits for this method of work / soldering. I have heard that someone actually produced such a training kit.

Also, a list of hints for tools, bino magnifiers?, OK what power?? Favorite solder station, and working temp?? things that make smt easier. wax on a toothpick, ok, kool but scary.

Ok, just my dream to put me over the edge and past the fear factor of the unknown and get me into the 3b kit.

tnx fer any considerations,

Feel free to email me with any questions about the build when you get to it. I like to use a magnifying desk lamp. I think it's about a 3 diopter. Some times I use the flip down magnifiers that you wear on your head. (Don't try to adjust it with a soldering iron in your hand, I burned my ear! Don't laugh!) The hardest part to mount is the DDS chip, the leads are half the pitch of the rest of the parts and it's kind of expensive, about $10 I think. Use the thinnest solder possible. Steve includes some with the kit. Radio Shack sells .015 that works well too. I use a regular cheapo Elenco soldering station or my old Radio Shack iron. The size of the solder is more important than the size of the tip. I like a chisel shaped tip because it transfers heat faster than a pointy one. I like to work with a hot iron and work fast.

Many people on this list have used the Cash Olsen toaster oven/hot plate method. The results are amazing, it looks like a factory job. I don't do this because I get a lot of enjoyment out of soldering. This group is full of people who know much more about these rigs than me and there will be no shortage of help.

For the record, I've built and ATS-3, 2 ATS-3A's and one ATS-3B. I currently own the 3 and the 3B. I would like to sell the 3B if anyone is interested ($190, pictures, details on request). I have a K3 on the way, got the Katiegram last week!

I received that ATS-3B about a month ago and it made its first contact today! I went down the street to Ulistac Natural Area, Santa Clara, CA, and hung a wire dipole off some branches and started calling CQ on 14.060. N7VOE in WA quickly returned my call and we had a quick QSO. This was also my first CW QSO in about 6 years since I moved out here from the east coast. This is a great little radio that I had a lot of fun building. I'm looking forward to it coming with me on my next backpacking trip.

Nick,

We actually don't yet know how incredible these radios are! We're just beginning to explore what can be done with small, portable, efficient HF radios.

If you keep going outside with your ATS rig, and using it in new places, you'll soon be exploring relatively new territory.

Remember that this is solar minimum, and there are no sunspots. The ultraviolet flux from the sun is at rock-bottom, and our ionosphere is much less ionized than it will be in a few years. When the sunspots come back, and we can utilize fine propagation on the 17 and 15 meter bands, we'll be working DX all over the world with almost no radio at all.

In the Flight of the Bumblebees event last weekend, I worked a whole bunch of fine ops from a small mountaintop near here, and my ATS-3B performed perfectly in the noontime summer heat. I was running 12V in, 5W out, and the whole box was warm! I worked 33 states and provinces in 4 hours, and made more than 80 QRP-QRP contacts, sitting in the pine trees. All my radio gear weighed only a few pounds, and the ATS rig was an insignificant part of the total! The antenna, feedline, and related items are now the limiting factor in portable operation.

Every time I take this rig outside and set it up somewhere new, it blows me away! I really hope you have similar experiences, which are virtually guaranteed if you use the radio outdoors.

--- In AT_Sprint@yahoogroups.com, "Par" <sitefix@...> wrote:

W3PAR,

I built my ATS-3A using a pointed iron and fine solder, one joint at a time, and it worked/works great. Just use plenty of really bright light, use quality magnification, use good tweezers, and practice on some junk SMT boards before starting the assembly.

After considerable uncertainty I decided to build my ATS-3B using solder paste from Cash Olson and a hot air embossing tool from Hobby Lobby. I placed most of the parts and reflowed the solder on Halloween night, with the critical melting happening right at midnight, by some strange twist of forces beyond my understanding. After touching up a few bridges, I went through the tests and alignment, and the radio ran perfectly, with no significant issues related to assembly!

There is a HUGE amount of material on this group site about the various methods of assembly, the tools, issues, etc. Many of us posted a whole lot of discussion material months ago, when we were building our rigs. We've traded a lot of ideas in a very positive and pleasant way.

Although it will take some time to find and read our posts, you might want to dig through what we wrote, if only to get some confidence, and to realize that most of us (at least those who posted stuff here) had a good experience!

We aren't going to write all that stuff again, but it's all here, and all you have to do is to use the easy SEARCH feature to find a whole bunch of useful comments and tips. Of course we don't all agree on details and methods, and some builders are much more conservative than others....

The best advice we have is:

1) Order a Norcal dummy load and build it. It's a good, accurate dummy load, and it lets you make decent power measurements as well. You'll gain confidence from this low-cost project.

2) Get some junk SMT boards and practice removing and resoldering the parts.

3) Read Steve's manual carefully, and follow his instructions. Most who have had problems did not do this well enough.

4) Once you have your ATS-3B rig assembled, don't flex the board.
This is a known killer of SMT parts and boards.

5) When you get your rig working, search and read all the volumes of
stuff here about the filter modules, the overcurrent detector, using
tuners, batteries, etc.

6) If you get stuck or have a nasty problem, post to the group here,
since some of us still check this site occasionally, even though
we're mostly using our rigs now, not building and adjusting them.

If you get through the whole thing and spend some time adjusting your
radio, there's a good chance you'll agree that it's one of the
greatest kits ever sold. It's also a ticket to new radio
experiences, if you take it outside and go portable.

Come join the NAQCC and help us in our mission to preserve and encourage CW activity on our amateur bands. The NAQCC (North American QRP CW Club) is for ALL CW enthusiasts around the world.

Our members include "Big Gun" contesters, hard-core QRPers, experimenters, ragchewers and SWLers; young and old alike. As different as we may be, we all share one thing in common, and that is our love for CW.

We welcome all who want to help support CW and have at least some interest in using QRP from time-to-time. Our club runs monthly sprints and challenges. Plus we sponsor some additional special on-air activities during the year.

Membership is free and once you join you're automatically a lifetime member! So sign up today and help us keep CW alive and well.

Visit our web site at http://www.arm-tek.net/~yoel/. You'll find info on our various activities plus an online membership application.

We look forward to your support and hope to soon see your call added to our membership roster.

From: pks57
Topic: 3411 Message: 3411

Hi,

in order to participate in a VLP contest I would like to reduce the output power of my ATS3A to 1W. Using an attenuator at the antenna output seems a very inefficient way as it would draw unnecessary power from the battery (portable operation).
The output power is also reduced when lowering the input voltage, but I'm not sure if it can be brought below 1W while having still enough voltage to keep the rig working (haven't tried yet though).

Any suggestions? Of course a reversible solution would be preferable.

thanks and vy72, Peter / HB9TVK

Peter,
The ATS-3A will put out about 1 watt with 6V in. That is high enough for everything else in the radio to work. Adjust the spacing of the windings on the toroids if you need to go up or down a bit to get at the 1 watt level.

--- In AT_Sprint@yahoogroups.com, "pks57" <peter.kohler@...> wrote:

Peter,

The ATS-3A and ATS-3B will run very well with about 6.0V applied to the power connector. My ATS-3B puts out about 1.2W on all the bands when run off a regulated 6.0V supply. I have posted a set of data showing power outputs for 6, 9, and 12V on the various bands. Please see the FILES section for the numbers I recorded. Your results will depend on how you have adjusted your filter modules.

The power output can be varied by adjusting the transmit toroids of the filter module for the band you're planning to use for the low-power event.

If you need a bit of attenuation, just add 10, 20, or more feet of RG-174 coax to the output. Using this coax will allow you to shave off a little power if needed. According to the program Transmission Line Details, at 14 MHz 16 feet of RG-174 will reduce the power by 0.1W if the input is 1.0W, assuming a 50-ohm load. This is about .46 db. The ARRL program TLW has slightly different data and yields a slightly greater loss, so you may want to verify your power with a meter if you use RG-174 for the "adjustment". Of course an attenuator using fixed resistors would be easy to make for the 1-watt level.

The minimum supply voltage is 5.5V, according to the manuals for both ATS-3A and -B. If you go below that, you may/will experience a variety of problems. Remember that the transmitter will pull down your supply voltage when you hold the key down, so you have to make sure that you have enough voltage - do some tests on your particular DC supply. I don't recommend using any kind of weak batteries, since the voltage will eventually fall below the minimum when you key the rig, causing it to stop running, just when you need it to be there for you.

If you're using an ATS-3A, be sure to check the keying at low voltage. The mod I did on mine to improve the keyed wave when running on 12V made the rig useless at 6V. I still need to implement the shaping circuit Steve used in the "B" model - that is a nice improvement.

If by some chance you have a QBSA, you can just turn down the supply regulator "knob" to get the power you need.

I have am Emtech ZM-2 ATU that is not working. Built this awhile back but never got around to testing it ....my ATS 3a works quite well with my tribander so I really never needed it..until now I would like to use it on 40 with an inverted V.
Anyone out there with experience with one of these that would be willing to have a look and see if they can get it cooking?

John,

I'm currently building the ZM-4 from www.qrpshop.de, a derivative of the ZM-2.

What exactly do you mean by "not working"?

As a preliminary exercise, did you try to match different resistors (such as 10, 22, 47, 100, 220, 470 ohms)? From all what I've read so far, the Z-match is very delicate to adjust because it's a resonant circuit.

Dear Rob and Carey,

thanks a lot for your input. I made some measurements and can confirm that it works as you suggested!

I first tried to use 5 NiMH cells, however fully charged they're delivering 6.7V which resulted in an output power of about 1.2W (after ca. 40ft of RG174 into a dummy load). While discharging they were dropping below 6.0V which isn't good either.

Using a stabilized source of 6.0V resulted in exactly 1W on 20 and 80m, and about 870mW on 40m (seems the 40m module is not optimally tuned).

So I'm going to find some decent DC-DC converter and will use one of the 11.1V or 14.8V LiPo packs I've got around here. So I'll be able to avoid the voltage dropping below 6.0V too soon.

Thanks again and best 72,

Peter / HB9TVK

It has been a bit of a disappointing wait for the Hanoi officials to get my license materials to VX2A in Saigon, but it looks like I will be on the air with my 3B most probably as VX2OC next week. I don't expect to be able to reach any in the States, but have been hearing a lot of JA, HL, HS, and UA calls in my pre-licensure QRL sessions from hotels and the beach.

My CSCE (the little ephemeral slip that is issued upon passage of exam elements, but superceded by the license itself) was required, and I had to have it dug up in the States--which took a long time. Anyway, I'll have an end-fed 50-foot wire with counterpoise, and probably be touching some JA ops next week from wherever we are.

The OC in this call, if it goes through as planned--is for Oscar Charles, the little rascal who's spending his 8th month on the air, as it were--travelling with us in Vietnam.

Is this at least the first ATS rig fired up in Vietnam?

Maybe that's something.

Peter,

An easy but inefficient solution is to use a simple linear 3-terminal regulator, such as an LM317T. This will drop the voltage to whatever you choose, as long as the desired voltage is more than about 2.5 volts below the input voltage of your battery.

The current available is over an ampere. A heatsink should be used to limit the temperature of the device.

I have several homebrew bench supplies based on the LM317T and similar IC's, and they do a nice job. If you use a multiturn pot to adjust the voltage, you can set them very accurately.

Of course, a DC-DC converter would be more efficient. I like linear regulators because they don't generate any significant RF noise.

If you're in a hurry, the ATS rigs will run with a resistor in the supply line. This is one of the few rigs that can deal with a resistive supply. Try about 5 ohms for a starting point, and adjust it to get what you want with the key down. You may be surprised how well it works! I was...

I have a resistor in my lithium ion battery box to lower the voltage for tuning or other situations where full power isn't wanted.

I checked the keying, the note, the stability - works fine!
Incredible radio - very nice design!

If you use an LM317 or similar, there are circuits which are more efficient - they use the device as some sort of switching circuit. They are >80% efficient, rather than just dropping the voltage via a "big regulated resistor" as is the case when you use them as a nominal 3 terminal I've used a LM723 plus pass transistor in such a circuit, but haven't experimented with the LM317 or similar.

All in all how many ATS-* have been produced?. I was just reckoning that the ratio of the number of members in the group to the number of radios produced is probably the higest in the world showing the fantastic interest in these cute wee rigs and the loyal following they have. We can certainly beat the "big boys" hands down (ken-su-com) and probably our only closee competetion would be Elecraft.
I've now got the new fine point iron ready to be flashed up here and the kit is screaming to get opened and started (I've built Blue Rose SMD kits before and it mostly doesnt look to bad but I do admit that the miniscule DDS still scares me. Lets hope the solder wick works well!)

NAQCC Sprint Tuesday night!
This coming Tuesday evening will be the monthly NAQCC Sprint for August, 2008.

I will refer you to the proper URL:

http://www.arm-tek.net/~yoel/sprint200808.html

There you will find all the details as to time, frequencies and also a special prize (a classic book in Morse on CD donated by Chuck Adams K7QO).

This month's Special Award goes to the winner of a drawing among the following: The member in each division who makes the highest score and uses a vintage straight key.

This is a monthly event that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate (this includes QRO); but you must use QRP power levels to compete for awards.

Come join us and have a real good time!

3426. My Radio Went Stone Dead

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-08-10 04:25:03 UTC
From: radio_kx0r
Topic: 3426 Message: 3426

Today I was sitting on a high mountain ridge calling CQ on 20 meters. I had tuned up an experimental vertical half-wave antenna in a tree, and everything seemed fine. The BLT match was almost perfect, and the temperature was about 80 degrees in the shade of the pines. It was a lovely place to operate, with the Plains and cities 1500 feet below.

Suddenly my ATS-3B went dead while I was sending. It was instantly silent with no warning, no smoke, and most important, no letter "E" on the display. Removing and restoring power had no effect. The radio was dead.

As I packed up my gear and hiked home through the woods, I wondered what could have happened to kill my rig. True, I was running 12 volts from 3 charged lithium-ion batteries, and yes, I was getting 5 watts out. But I did that for 4 hours in the Bumble Bee event, and the radio didn't die then. Maybe the stress of that event...

When I got home, I checked the battery, and it was totally dead - zero output. What? How? After I opened up the box containing the 3 cells, I found that 2 of the cells measured about 3.96 volts - this is OK. However, the third cell was almost dead. Since I used a protective PCB in the pack, the protection circuit had turned off the pack. I have no idea why the one cell went down, and I know I didn't charge it above spec - but at least the protection worked.

Be sure you use protection PCB's if you use lithium cells in homemade packs!!

I tried the radio with another battery, and it's perfect!

Too bad those lithium cells are held in there with silicone...

Whew, Carey, that was a close one! Knowing the way you run your ATS,
that was the first thing I thought of, too. Thanks for the heads-up.

72, Dave K1YHR.

3434. Re: [AT_Sprint] Has anybody gotten the Jornada 720 to xmit psk with the ATS3B?

Hi Bill.

The output amplitude of Jornada 720 is too low to trigger the paddle input pins directly. You will need to build the slicer interface, look at the page 31 of the manual. Make sure that you install C1 of the slicer. The sound output of Jornada has not only low amplitude, but is also noisy. I spent about two weekends debugging communication with my Jornada 720. First I thought the interface does not work because the Manchester data stream is distorted by Jornada's equalizer. I even tried to develop an algorithm to predistort the Manchester signal to counter equalize the equalizer phase distortion. Incidentally I found out, that a 560pF capacitor to the ground fixes the problem and now the communication works. After you build the slicer, you could try to play with Jornada's equalizer to lower the rest of TX errors, if there are any left. If you connect Joranda's output to a scope, you will see short and bumps. The short (0.25ms) bumps shall have approximately the same amplitude as the long (0.5ms) ones. There shall be minimal phase shift between the long and short bumps.

I am currently developing some hardware and software extensions of ATS-3b. The first will be variable bandwidth filter. I am doing my extensions by Manhattan method on the bottom side of the board. I am using strips of gold plated connectors of PC memory modules and PCI boards. They have the same spacing as the SOIC chips. I am using magnet wire to interconnect the islands. This way you could fit slicer and much more on the bottom side.

I already fitted 74HC164 8-bit shift register on the bottom side and rewired 7segment display to it. Now I have 7 CPU pins liberated for other tasks. Two of the liberated pins will be used for I2C bus to drive D/A converter of variable bandwidth filter. I already have some electronic pots chips home, which I will be using to control earphone and digital interface amplitudes. The pot will be programmed separately for RX and sidetone, so this will also allow user control of sidetone volume.

Hi Vojte(ch,

Thanks for that and all the rest you have done for us. This is a great
setup and
your software coupling to this radio is one of the main reasons I was
excited to
get it. I will build the other interface and try that.

Good luck with the other developments, as well.

73,
Bill, ni5x.

Bill, ni5x.

3437. odd behavior on band modules for ATS-3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-08-11 17:41:22 UTC
From: John Shadle
Topic: 3437 Message: 3437

I have completed my ATS-3B and was trying to make sure it all worked as I drilled my Altoids tin. Something odd is happening, though, and I would love to get some troubleshooting advice for this issue.

My 40m and 80m band modules give the "4" and "8" when powered up. That's where the good times end, though.

My 15m, 17m, and 30m modules do nothing upon power up. My 20m module provides "8" on power up.

I was pretty sure that I didn't stuff any wrong parts, but maybe that is the problem. Any help would be appreciated--hopefully something that doesn't require me getting the microscope out and my soldering iron. Hi hi.

Measure resistance between pin 3 and pin 5 of the band modules. Then compare with the chart at the top of page 21 of the manual. Let us know the results and we'll go from there.

Is it possible that you did some of the tests with fast power resets? That could account for not hearing anything. You should at least hear an 8 if nothing is inserted. When the power is disconnected it might be a good idea to hold the menu switch closed for a couple of seconds so that the caps are discharged. This will make the power on not think its a high current reset.

John,

I had a similar problem where my 30M module was recognized as a 40m module and my 40M module was seen as an 80m module. The other bands were OK. Upon investigation I found a very thin solder bridge across pins 4 and 5 of U7, the 5v and 3.5v lines. So perhaps you have a bridge somewhere as well. Did they ever work properly?

Michael,
I can't find the values on Page 21 that you speak of. I do see the table indicating which resistor I should put on each band board, but nothing else--and those values don't necessarily correlate with the values between pins 3 and 5 on the band boards.

Please let me know if I'm missing something or just plain confused. ;)

It's definitely not an issue of the power reset happening. I waited quite a while between power ups after changing band boards. Wish it was that easy...

Thanks.

The resistance between pin 3 and pin 5 should match the table that has the values for RF1. (Example the 30M board should read about 10000 ohms). This is with the boards NOT plugged in. If you don't get the correct ohm reading then you either have a wrong/bad resistor or a short somewhere.

On the bottom of the board you can see the trace from one end of the resistor to pin 3. Pin 5 is ground.

Did it ever work properly?

I recently heard some FeldHell transmissions on 40 meters and was unsuccessful in copying them with PocketDigi. Multipsk did decode the FeldHell signals.

Has anyone had success with FeldHell and the ATS3B? If so, how does one get PocketDigi to paint the screen with received characters?

Hi Full (hope this is your first name)

The Feld Hell reception is not implemented in PocketDigi and I am not sure whether the Feld Hell TX works with ATS-3b. It is basically fast CW, but I am not dead sure whether the manchester protocol is fast enough to support it.

http://groups.yahoo.com/group/AT_Sprint/cal

Run for the Bacon
Sunday August 17, 2008
6:00 pm - 8:00 pm
(This event repeats every month on the third Sunday.)
Location: Your shack or anywhere

Notes:
This Sunday evening, the Flying Pigs Amateur Radio Club International will be holding its monthly Run For The Bacon. This is a friendly, two hour QRP CW Sprint, which is open to ALL radio amateurs, will last from 9:00 - 11:00PM EDT (0200-0400 UTC Monday).

You may work stations once per band on 160, 80, 40, 20, 15 or 10 Meters. Suggested starting frequencies are 1.812, 3.562, 7.044, 14.062, 21.062, and 28.062 MHz.

The exchange is RST, S/P/C (State, Province, Country) and Flying Pigs membership number. If you're not a member of the Flying Pigs, and would like to be; then please cli

3450. ATS-3b with rotary encoder and other experiments

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-08-18 03:18:23 UTC
From: Vojtěch Bubník
Topic: 3450 Message: 3450

Hi gang.

I did some more enhancements of my ATS-3b. I am using an extreme Manhattan construction with SMD parts, magnet wire and pieces of computer PCI and SIMM PCB connectors. Here are the pictures of top and bottom side of the ATS-3b main board. Click on the picture to zoom it.

http://www.kufr.cz/~ok1iak/temp/ATS3b-Manhattan-Artwork-in-SMD/

I currently added a cheapo rotary encoder for main tuning and microcontroller regulated voltage regulator from 0 to VCC for biasing of varactors in variable bandwidth IF filter. Tune Down button is currently used to switch the rotary encoder between tuning and bandwidth control functions.

I added shift register between microcontroller and display to free some of the microcontroller pins. Now I still have 3 pins free, but they will be used soon. The D/A converter is an I2C part and other I2C parts may be controlled at the same pins as the first D/A.

The rotary encoder works as a charm. The part I used is Mouser's 858-EN11-VNB1AQ15 for $1.34, 20 pulses per revolution with detent. I removed the detent and checking for all up/down edges of the A/B signals I am able to detect 20x4=80! positions per revolution. It really works well, I am surprised and happy about it. The encoder rotates smoothly, is cheap, small and still seems to be robust. The encoder will fit for sure on the side of the Altoids tin next to the RCA connector. The encoder is so thin, that I believe it will even fit between the PCB board and the front side of the tin.

The varactor bias circuit is a bit complex. The D/A converter operates at 3.5V. Its output drives an MCP601 op-amp at 3.5V, which drives two transistors powered by ATS main power supply. This way one gets as high varactor bias as possible to open the filter wide. Still the power consumption of this circuit is about 0.6mA.

Now I will be experimenting with better matching of the crystal filter to get nicer filter shape at wider bandwidths. I will also reconfigure the audio amplifier as low pass to allow for SSB reception. Then I will add a separate switchable CW audio filter and digital pot for volume control. The volume will be controlled by the rotary encoder also.

Date: 2008-08-18 03:37:24 UTC
From: shadle
Topic: 3451 Message: 3451

Hi (again),
After solving my soldering problems since I last wrote, I have the board in the tin and am trying to adjust band modules for peak power.

My issue is not when I enter straight key mode on power up (i.e., hold down the dash paddle while powering up). That works great. I'm getting 6.7V into my Elecraft DL1 (1.8W) from an 8.0V battery, which is okay.

The issue is when I plug in the power and am trying to actually "use the radio". Pressing the MENU button does nothing--but when I touch either the dash or dit paddle I get the following output:

S N D P A (and S n d P A on the screen)

Now when I press the paddle or MENU button (or any other button for that matter) nothing happens.

Any ideas on this one?

Thanks.

John,

Not enough information to pinpoint a specific area. Here is what I would do:

1. Take the board out of the tin.

2. Test without paddle, to make sure that all buttons work as expected.

3. Test with paddle.

4. If it works, then check the mechanicals of the tin/board relationship for some kind of short.

If any of the above steps fails then report the results back here and someone will try to help.

Btw, the N is likely an M, right?

> is it possible to use the rotary encoder without software
> changing at the ATS 3 (not ATS3B) too?

Hi Harry.

My extensions of ATS-3b certainly include both hardware and software. Your ATS3 has all microcontroller PINs used already. To connect the rotary encoder, one needs either to multiplex existing pins to free two of them for the rotary encoder (that is what I did and I had to change software too), or you need to simulate up/down buttons with the rotary encoder.

It is possible to connect some of the rotary encoders with detent directly to the up/down buttons. They have both contacts open in detent position and one signals goes down first if rotating from detent position in one direction and the other goes down first if rotating from detent position in the other direction. But if you slightly press the shaft out of detent for one second, ATS3 will initiate fast tuning, which is an unwanted effect. The mechanical encoders with detent have usually low number of steps, about max 25. If you remove the detent and modify the firmware, the decoder will provide 4x more positions.

One could program a small microcontroller to read the rotary encoders and simulate up/down buttons. Putting the new chip between the rotary encoder and up/down buttons of ATS3 will not require any change in ATS3 firmware and will work reliably. I thought about this possibility first and I even found some example on the internet. But now I went another direction with my ATS3b.

73, Vojtech

> 2. Test without paddle, to make sure that all buttons work as expected.
> 3. Test with paddle.

Here is where it got weird. I went back to page 22 of the manual and decided to do the Check Out and Calibration steps again. I removed L3 and found no shorts between DC in and the 5 and 3.5 V regulators. Plugged in power. Heard the "8" (and saw it on the LED). Voltage at TP1 was 3.97 V. Voltage across PA gates was as expected.

Now is where the odd stuff comes in...

I plug in the paddles and immediately get the SndPA on the LED display (and SMDPAX in the headphones). After this point, neither pressing any of the four buttons nor tapping the paddles results in any noise or action with the radio.

I decide to see what happens if I leave the paddles out. I remove the paddles and try to plug the power back in. It appears that the voltage protection has tripped, so I press the four buttons to reset the protection and then re-apply power. I get "8" audibly and visually. I then press the MENU button and get SMDPAX in succession.

I did this last step again and found out that I can hold the MENU button down and will be able to access various functions by releasing the MENU button when I hear/see the menu item I'm interested in; however, after I choose the menu item (e.g., "d") then I can only exit the menu and after that, no joy.

This is very frustrating. Any suggestions would be greatly appreciated. I'm sure it's something simple, but I really am at a loss at this point.

> 4. If it works, then check the mechanicals of the tin/board
relationship for some kind of short.

I think this is limited to the board itself and not the tin/board
mechanicals. No short there that I can tell.

> If any of the above steps fails then report the results back here
and someone will try to help.

Hope so. I can't figure this one out. I'm sure it's something simple.

> Btw, the N is likely an M, right?

Yes. It "says" M but "writes" N. That's what I meant to type. :)

Thanks for all your help, Mike (and whoever can figure this mystery
out and help me get on the air with the 3B).

3456. Finally got psk transmit with jornada 720 and ats3b.

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-08-19 03:32:06 UTC
From: Bill
Topic: 3456 Message: 3456

Had to use an audio amp between the output of the
Jornada and the simple interface to the ats3b. I built the
more complicated interface with the op-amp, but it isn't
working yet. I either have a bad op-amp chip or (more likely)
I have bad solder joints. I am using a surface mount AD8692 that
I got as a free sample.

The audio amp I used that was successful uses TDA1517P chip with
fixed gain. So far I have only transmitted into a dummy load.
I will post to the group again when I have a successful QSO with it.

73 to all,
Bill, ni5x.

I would check with a multimeter that there is no extra connection
between inputs and outputs of MPS430 that could result in this kind of
behaviour. P1.0 and P2.0 could be shorted under the chip for example
or something similar.

From: Kurt Savegnago
Topic: 3451 Message: 3458

Any idea when Steve is going to return? I saw the post on his webpage.

He fixed my 40 meter DSW-II for me and worked great on the dummy load.

Took it out and tuned my PAC-12 with the variable coil to 40 meters with an SX-600 meter and an FT-817ND to a nice low SWR. Went to the deck, brought over the DSW-II plugged in the antenna,phones and key applied the power.

I heard a "dit, dit" then nothing. Looked over at the antenna and the tap came off the coil! The DSW-II is now dead. I think the power was set to the max 5 watts and the power supply was a 12V gel cell.

Was wondering when Steve was getting back as he does repair work on these units according to the Small Wonders site.

He previously fixed the unit as there was a micro piece of solder shorting one of the 2N7000 transistors. It was trying to transmit in the receive mode. Once he brushed it off, the radio worked nominally.

I really tested it out on the dummy load when I got it back from him and it worked absolutely beautifully. I want to send it back one more time to see if he can bring it back to life. Next time, I'll turn the power trimmer to low while on the dummy to help prevent this from occurring again. Plus double check the antenna first. This is probably going to be the most expensive DSW-II 40 meters out there! :-)

3459. SMT resistor question

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-08-19 23:51:44 UTC
From: n8ewy
Topic: 3459 Message: 3459

This is my first post to the group. I just started working on my ATS-3B and I already have Shot one of the small(0603 size) 47k (labled 471) resistors into SMT never-never land. Of course I couldn't find it.

I recently ordered a couple 500 piece smt grab bags from Dan's Small Parts. I found 3 or 4 471's in it. They are just a hair larger than the ones in my kit. The difference is negligable. It fits on the board just fine. By that I mean the contacts on each end of the resistor fit to the pads on the board almost as well as the original.

Is this resistor going to work OK on the board in place of the loast one?

It will work fine Dohn. I've done the same thing, except I can go down to the local Fry's and pick up the 1206 size. As long as you can get solder on the pads and on the ends of the resistor you're fine. In a pinch you could even bend the leads of a regular resistor and solder it on to make it work in an emergency (or while you're waiting for the right part).

In resistance, size doesn't matter ! :-) Seriously, all else being
equal, it should work fine. It's probably a metal film 5%. Most 5% measure
closer to 1% tolerance anyway these days.

You guys right. It was 470 Ohms. Thanks alot for the assit. I doubt if this will be my last question regarding my build. So far I'm loving working with these smt parts. It's not my very first experience with them, but it's the most complex. I'm taking my time and experimenting with diff methods of building. So far a pair of tweezers and a couple toothpicks are working best for me.

I'm open to any sugestions since most everyone here has completed one of these great rigs. I am considering combing it with an FCC-1. I have one built which I built in combination with an FCC-2. I sent the board off to have the large (small sized) processor soldered down. I admit I was intimidated by it.

I ordered a second FCC-1. I'm still thinking about shipping it off to have the fine precessor placed. If I do, I may send the ATS as well to have U7, the DDS chip, soldered.

If there is someone here on the list that would be interested in the job, PLEASE, by all means let me know. If anyone has any suggestions on how I might do this myself, I am open to that as well. I just don't want to spend weeks troubleshooting my rig. I am still quite an amateur at this and I am a good solderer. However, being an amateur at building means I am not real experienced with trouble shooting. I have built an RF probe and I'm learning to use it, but I have alot to learn about theory. I'm motivated.

Once again, if there is someone on the list willing to take on these couple of soldering jobs, I would be willing to chat about it. I really want this thing to work good.

Thanx for the bandwidth

Dohn,
Don't be intimidated by the small pitch of the DDS chip. You can tack solder it at opposite corners and then do the rest of the pins. Let the solder bridge. Go back over it with some braid and it will look perfect. I've used that trick before but haven't had to on the ATS's I've built. The magnifying lamp and tiny, tiny solder is your friend.

I totally agree with you Mark. I do not use a superfine tip. I use the tip that came with the soldering iron. I like to keep it on the hot side and work fast. For SM, I use solder that is .015 or .010. It's very easy to get too much solder on a joint with SM components.

Hi Dohn.

One advantage to work with SMD is that it makes the junk box small and easy to obtain. Just keep couple of computer cards on hand. It is easy to find a missing resistor on the junk box boards using magnifying glass and good light source. No need to buy set of parts at all. To remove two leg SMD part from the board I actually add solder to both ends so I may heat both ends at once with a soldering iron. After the solder melts I push the part away and it will stick to the tip with surface tension of the solder. Then just shake the part off the tip, pick it with tweezers and remove the surplus solder with clean soldering iron. Finally it is wise to measure the part with a meter. If one works fast and does not use excessive force during desoldering, most probably the part will be OK. But if you push the part before the solder melts, or heat just one side of the part, you may peel off one of the contacts.

Vojtek,
It sounds like a flux pen is in order. I think I have one in my shack. Do you guys have a preference for solder braid? Is there something/some kind that is superior to the others? What I have, I got from DigiKey. It works OK at best. It takes a short period of time to get the solder wet and then to wick.

Would it help to swipe the joint with the flux pen first?

I am using a solid rosin. If there is no rosin on the solder joint I want to free off solder, I first put the wick on the rosin, heat the wick with soldering iron and let it suck the rosin. Then I place the wick over the joint and warm the wick with soldering iron. The liquid flux will work as well, maybe better. There are wicks sold, which are already filled with flux, but the flux-less works well for me. I don't think the wick type is important as far as it is not corroded.

From: shadle
Topic: 3451 Message: 3471

Here is the resolution to the problem posted a few days ago. To recap, I was having strange behavior with the MENU functions starting when I used my paddles. I also found that when I torqued he board just a bit I was able to use the MENU button.

After some troubleshooting help from W1MT as well as KD1JV I found out that I must've had a not so great connection on one of the resistors near PB1. Here is Steve's reply about getting the MENU button function from keying the paddles:

"Check the connections to the pull up resistor on that button. Torquing the board likely makes it connect, which makes the button work. When it looses connection, the input is floating, which is likely why the keyer makes it trigger sometimes, due to leakage."

Interesting stuff!

Can't wait to make my first contact with the rig. Now to finish calibration...

Take care.

3474. Green trimmers in kit???

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-08-23 21:56:27 UTC
From: n8ewy
Topic: 3474 Message: 3474

There are 9 green trimmers in my parts for the ATS I am building. What I don't get is if you mount them according to their design, the adjust screw inside the cap is on the bottem and can longer be adjusted.

Do you modify the leads or am I missing something?

Hi Dohn.

It is a known issue. One of ATS-3b batches contains those trimmers. I remember Steve ran out of the correct ones and he was unable to obtain the same type. His recommendation is to solder them to the other side of the board, tune the filter, remove the trimmers and solder them to the bottom side of the filter board.

Hi Vojtech

I know I saw this addressed at some web page, but I can□t remember which it was. It had pics.

I still cannot picture any way to mount this cap and have the adjustment side (bottom) of the cap facing up for adjustment. Not without bending the leads of the cap 180 degrees. Then the flat side could face the right direction and the adjustment screw would be accessible. It seems like It would be hooked up correctly as far as polarity goes. (Flat side facing the right direction)

I think it was Wes Hayward, W7ZOI, who ran some experiments and found that the clear, electronic grade, RTV was the best adhesive he could find. I also use hot-melt glue without a problem. If I remember correctly, he wrote a report about it and you can find it on his website. Do a Google to find it.

I've never felt the need to secure the toroids but think double sided tape or thin double sided foam might be fine. It would also be easily removable if the need arose. Than flexible goop that is used to hang light things on walls would be easy to use as well.

Alan,

I did Q tests with a set of toroids and showed that there is very little difference in performance between inductors coated with nothing, hot glue, silicone, Duco cement, and 5-minute epoxy.

For the ATS-3 I like hot glue, because an inductor can be easily removed using hot air. The glues are too permanent, especially when you understand that whether you get 3.5 or 5 watts from your rig on some band may depend on how well you adjust the turns or those two toroids in the transmit filter.

Whatever glue you use, use a minimum amount on just one side.

The little filter modules seem less delicate once the toroids are glued down. The turns will definitely get moved around and detuned if you change bands often in a field or outdoor location. You don't want your toroids pulling loose from the delicate board. You should be able to replace a toroid if it gets damaged, and I think your choice of glue should be made with that in mind.

Whatever you do, don't rush and glue any of your inductors until you've had time to adjust the turns and optimize them. My papers relating to adjustment of the filter modules are posted in the Files section of this site. Whether you want maximum safe power or best efficiency, you'll be very pleased if you patiently adjust your output filters. Some improvement in receive performance also is possible - your starting values may not be quite right on every band.

There are a lot of posts on these subjects, plus other good stuff you can find, if you use the Search feature for our site.

For mounting a medium or high-power inductor, forget hot glue - it will melt when the inductor gets warm. I like silicone (RTV, etc.) because it absorbs shock, can take some heat, and tends to keep the toroid where it belongs. It's really a pain to remove, especially if you go heavy with it.

Which ATS? If it's the ATS-3B, the filter boards should have a hole
where each trimmer is mounted, so you can reach the adjustment screw.
The bottom-adjust caps are ideal because you can adjust it while the
cap and filter board are mounted normally.

3486. ATS3B Jornada 720 and Op-amp interface for PSK

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-08-26 02:12:16 UTC
From: Bill
Topic: 3486 Message: 3486

Some on here asked me to post when I got the Jornada 720 to work psk with the ATS3B. I now have it working using the op-amp interface as listed in the manual. It is the same schematic, I just used a different op amp that I had on hand. I used a AD8692 that I got as a free sample from Analog Devices. I built it surface mount, manhattan/ni5x style. There is a photo under my call sign in the photo section. It is very ugly, but works. It is made to fit inside a small altoids tin and run from 3 volts.

feel free to ask me about it, just don't expect expert answers.
73,
Bill, ni5x.

3487. Sidetone volume.

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-08-26 08:43:03 UTC
From: kc7fys
Topic: 3487 Message: 3487

I recently had a really good time on a family trip in Vietnam, operating my ATS3B from the balcony of our beach bungalow--into a modest dipole. Worked lots of countries and naturally--a whole load of JA stations for about 5 evenings running on 40M. No other bands yielded anything to speak of, however. Great fun. Photos and description here:
<http://www.flickr.com/photos/jonathancharles/sets/72157606886612479/>

One issue for me was sidetone volume. I use a little Radio Shack powered speaker about the size of a Big Mac. It's the biggest piece of equipment in the tupperware pitcher that contains my station, besides the 10-AA cells, but I just can't deal with headphones. A lot of the problem is my own tinnitus, but the gain-riding is tedious, too. An in-line volume control works, but leaves me turning it up and down between hearing my sidetone and the receiver itself. I'm a sort of sound reinforcement appliance operator, too, and if the ATS3 were a synthesizer or any other instrument with such a wide dynamic range, I'd run it through a compressor with a really fast attack and decay to hard-limit the sidetone. There'd be pumping and artifacts, but at least the sidetone would be tamed. I found myself, when calling CQ on a frequency in beacon mode, having to quickly turn up the volume between iterations. The sidetone became too much of an attention-getter from other tourists!

I did a search of the yahoogroup and didn't notice a previous conversation. Is this something I might be able to perform a mod for? That seems like a better idea than trying to deal with compression, etc. This is a small thing in the big picture, though. What an impressive rig out in the field. Several Vietnamese hams and marine radio technicians gave it a thorough looking-over. XV2A, Mr. Nguyen, was looking for some inexpensive gear to encourage new hams to get started, and although the 3B isn't in the "cheap" category, I was able to suggest several single-band crystal-controlled QRP kits that could easily be built from parts available there.

Anyway, the sidetone thing. Any ideas?

Change R12 to 1M or higher.

Or put 330k or lower resistor parallel to C21. Lower value will decrease sidetone more. You could stack the additional resistor on top of C21.

I am currently working on a fancy digital volume control. There will be just one digital pot, but will be reprogrammed between RX and sidetone, so one would have a possibility to control both independently. But this mod is much more extensive than the simple resistor addition.

Yep. Except it is now R12 (in the ATS3b). Increasing the resistance
of R12 successfully lowered the side tone volume in mine.

Good Luck

3494. initial check out: OK on the digital display 8, but not the CW 8

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-08-30 19:53:00 UTC
From: Alan Shapiro
Topic: 3494 Message: 3494

My initial check out running off a 9V transistor radio battery that reads about 8V.

5V and 3.5V Regulators OK.
Display 8 on power up, but just hiss in the headphones. Also no tone with dits and dahs.
TP1 voltage is 3V, not the 4
The instructions say to check voltage on the PA gates, Q6 to Q8. Is that right or should that read Q7-9?

Looking for some help.

Thanks!

Hi Dohn.

> Any approx. ETA on that vol control?????????

I am implementing hardware extensions first with rudimentary firmware changes just to test the newly added hardware. I currently have the variable IF bandwidth control and volume control in place. After I have all the new HW working sufficiently, I will start polishing the firmware. With the rotary encoder in addition to the four existing buttons one could make the user interface more friendly. But it will be much more effort than it seems to. And my son is using a lot of my free time previously spent by homebrewing.

I reconfigured audio amp from Sallen-Key sharp CW band pass filter to a simple voltage follower configuration with amplification control by putting digitally controlled resistor at feedback of the audio amp. It works, but passes all the wide band noise generated by the product detector SA612 and all following stages into your earphones. I certainly do not like it. I will most probably add a two section op amp configured as SSB low pass and CW band pass filters and I will add a firmware controlled digital switch to bypass the CW filter.

I tried to receive SSB on 40m with the variable bandwidth filter, but it did not work well. The variable IF filter opens up. The BFO is set above the IF pass band, so at audio frequency the situation is inverted and the variable IF filter opens down. I believe Steve's design decision to put the IF below BFO frequency was driven by circuit simplicity. Putting the IF above BFO frequency requires additional pulling inductance. I believe I will try to pull the BFO below IF one day, which will make the SSB band correct at all bands but 40M. On 40M the side band may be flipped by injecting mirror frequency into the mixer, which is a simple firmware change.

I also fitted one jack socket between the brass spacer and earphone socket on the ATS-3b board. It will be used for digital control, but it is not connected anywhere right now. I will post pictures later.

Hi David.

> Your on-going development work is wonderful and I am following it with great interest.
> I have hopes that KD1JV will issue another kit incorporating your final modifications.

I cannot talk for Steve. I believe there is enough room for the additional chips on the existing board, but it would require 4 layer PCB with smaller vias to fit it all to the same format. The board will be much more expensive and the kit more difficult to build and debug.

Again, I cannot talk for Steve, but I could imagine if there is something to be brought to his kits, it may be the rotary encoder and / or volume control, but most probably not the variable bandwidth stuff or exact PSK31 envelope which is on my todo list.

One could model single quartz by series resonant circuit (piezo effect of the quartz) with a parallel capacitance (electrodes). A ladder filter modeled with just the series resonant circuit will be symmetric in log frequency. If one simulates ladder filter with real parts and added parallel capacitances of the crystal electrodes, the filter response will have deep notch on bottom side and will have poor response on the upper side. It is usually not a big problem and one uses the deep notch to improve sideband suppression. Therefore it is advanteous to put the BFO frequency below the IF filter.

Alan,

Are your 8V measured under load or is it the open circuit voltage of your battery? Let your ATS-3B measure and display the actual voltage. 40mA is quite a load for a 9V battery, so maybe what's left of your 8V is less than you would expect. Just a little hint to make sure you are not chasing a battery problem.

In my manual, regarding the filter boards, it states that Toroid LF4 should be an 18uH molded inductor (BRN/GRY/BLK). That is what was sent as inventory.

HOWEVER ..... in looking at suggestions from others (KX0R for instance) some have changed the molded inductor to a T37-2 with 75 turns of #30 wire. Have others done this as well for better tuning? I was wondering if I should dig up another toroid and do this as well?

Anybody have thoughts on this??????

Gang,

Not sure if this has surfaced before (no pun intended).

Unmodified, the OTTER (waterproof) BOX model 1000 (priced under $12.00) is such a snug fit for Altoids tin ATS-3 series with the phono RF output connector in place that there is no rattle, with the box sealed (gasket type seal). It is ever so slightly overdimension for a naked Altoids tin.

I operate some at Oahu beaches and this is a nice barrier box in this environment (when breezes with sea spray and light rain develop outside my Kelty tent). Kayak operation under construction!

SEE www.otterbox.com (no financial interest).

SEE operating site at www.campmokuleia.org (no financial interest).

Great enclosure Jerry, Thanx for posting it.

I've put my ATS3 in a zip lock bag with small holes, taped over the leads at the holes, and gotten by ok in rain. If I need more protection than that, I'm not going out, hi.. I'd be a whole lot more cautious near sallt water tho..

I love this radio stuff !

Jerry :

Checkout my pics in the photos section of this group (last page).
I use the Pelican equivalent to the Otter 1000 and
my ATS3A is in an American Morse AA-1 enclosure.

I have Pelican cases for most of the rigs that I use for portable
operating, as they are extra insurance when carrying the rigs around
in a pack or even the trunk of a car.

Cheers,

Michael VE3WMB/VA2NB

3504. P3 Touch Keyer inside ATS IIIB

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-09-03 14:30:40 UTC
From: kr5l
Topic: 3504 Message: 3504

Hi,

I am going to post 3 pictures of my ATS 3B with a P3 touch keyer installed inside. I used a Whitman's Chocolate Sampler tin -- it is thicker than an Altoids tin and gave me enough room to install an AC plug from a wallwart. The setup works just great.

All The Best and 73's,

Jerry Henshaw

It looks great, Jerry.
Where is the touch-keyer PCB? Mine had to reside stuck to the top of
the paddle jack. I don't see yours. Nice to have paddles close to the
ATS3 onboard buttons, too.

QRP'ers,

We plan to be QRP'ing on 20 meter cw later today and tomorrow (3 and 4 Sep) from the beaches of eastern Oahu.

Site of planned operation...see www.bellowsafs.com

More to follow here on QRP-L after we gain access to our beach house.

Operation later this month (18 and 19 Sep) planned from beaches of NW Oahu...see www.campmokuleia.org

From: Jim Fraser
Topic: 3509 Message: 3513

I haven't seen any Whitman Samplers, but I have not really been looking for candy too much. I did pick up a can of Sucrets earlier this year and put a N0SS Noise Generator into it. It is slighly deeper than an Altoids tin, but it is not as wide.

Sucrets: 3.25 x 2.5 x 1
Altoids: 3.9 x 2.5 x .9

The sidetone volume on my ATS 3A is killing me...As has been previously suggested I would like to replace the R11 resistor with something around 800K.
I have called several sources and they all want a minimum order..
So
Anyone have a type 0805 5% 800K smd they would like to part with?
I know I could use a regular resistor but I want things to match..
Thanks

Several comments:

Set yourself up for SMD by getting some of the assortment kits.
Collect scrap PCB's that have SMD parts. A PC or other piece of
consumer gear will have hundreds of useable parts.
Use a leaded part. Bend the leads appropriately and fit it to
convenient pads on the PCB.

I put an assortment of parts in the mail today. Let us know what
value works out for you.

3516. DDS reference oscillator 50MHz

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-09-06 00:58:59 UTC
From: Alan Shapiro
Topic: 3516 Message: 3516

Hi again,

I'm checking out my recently completed ATS-3b.
I see 60 MHz on the input to the DDS chip, and 50 MHz on the output.
I am looking for 10 MHz of course.
I do see 0.87V across R16 on the "CF" mode.

The other out of ordinary thing I see is 3.1 V on R19 rather than the "about 4 V" stated in the manual. I do have the 5V and 3.5V OK on the DDS chip.

Any suggestions please.

Alan, NM5S

3517. Wilderness Radio Operation with ATS-3B

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-09-06 03:25:50 UTC
From: radio_kx0r
Topic: 3517 Message: 3517

Over the Labor Day Weekend I fulfilled a lifetime dream of operating a ham radio station from a remote wilderness location on a backpack trip. While I've operated QRP portable from numerous tent campsites in the woods and mountains here in Colorado, somehow I'd never managed to take an HF station on an overnight backpack trip into a real wilderness area. It finally happened.

My trip was about 9 miles from the trailhead, into the Mount Zirkel Wilderness northwest of Walden, CO. Even though it was a major weekend, I had several square miles of stunning scenery, and three subalpine lakes full of large trout all to myself for more than two days!

The station weighed about 3 pounds and consisted of the ATS-3B, 5 band modules in a small metal box, a 3-cell lithium-ion 12V 2.2AH pack, a homemade ALT-type L-network tuner, Palm paddles, small in-ear hones, a 57-foot inverted-L #22 antenna wire, a 16-foot #22 counterpoise, a 100-foot 3/32" dacron rope, a 60-foot 3/32" dacron rope, and a small organizer pack for protection. In addition I took an extra spinning reel spool loaded with braided line for putting up the antenna, plus two large steel nuts for use as casting weights. These items had a dual purpose - putting up the third rope for the "bear bag" food storage.

The sloping INV-L antenna was about 33 feet high in a tree at its high end, and it sloped down to about 18 feet up in another tree. Then it came down vertically to the tent. The 16 feet of counterpoise was laid out on the ground away from the antenna. There was no feedline. I've used similar setups before. While Eznec shows it to be inferior to a center-fed dipole at 30 feet, it's less to carry and simpler to erect.

Operating the rig was the fulfillment of a dream I've had for almost 50 years. My first contact was Friday after dark on 40M with KB0QZ in Centralia, MO. He was 579-589, but he only gave me 529. Nevertheless, we had a nice ragchew lasting more than 30 minutes; Marty was running 30W with an OCF dipole, and he sounded great up there at 10,000 feet.

Saturday afternoon I tuned up on 20M and called CQ a few times, with no luck. The I heard DL5RBR working a contest, and I called him just for kicks. He came right back and we had a complete exchange lasting a few seconds - at least the rig was getting out on 20M. Later that night I tuned the antenna up on 30M, and had a wonderful, solid Q with NO8D/P, who was camping Labor Day Weekend with his XYL in Ohio. He was 599 with a 100W rig and a dipole, and he was solid all the time -

I had to turn down the phones. He gave me 569-589 with QSB, and we had a nice chat for quite a while. We were both intrigued to be portable and solid on 30M well after dark. After I signed with NO8D/P, AB9NZ called me and said he'd been listening in, and wanted me to know I was getting into the Chicago area real well. We gave each other 599's and exhanged a nice words both ways - he sounded like he was across the lake instead of across the Plains.

Steve Weber made this possible. He followed his dreams and worked hard to make this radio available to others. Thanks again Steve! The design of the ATS rigs is perfect for the type of trip where you can't think about taking an HF radio unless it's small and light. It's no rock crusher, but it's a real multiband performer on a simple wire once you get it matched. The control interface works fine in a dark tent, and the power consumption is incredible for a full 5W rig. After a total of 2 or more hours of operating, I used 10 to 20% of my LiIon pack - I was down to 11.8V. This thing continues to amaze me...and there are no sunspots now...wait til the new solar cycle gets going!

Hope this provides a little encouragement for some of you to put together a little pack with the stuff you need to go portable. At first, it's a little hassle, but it gets easier each time you go out and try it.

3520. Flux under crystal!!! and an open CAP at C41.

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-09-07 11:09:34 UTC
From: bruce.olney
Topic: 3520 Message: 3520

Howdy everyone!

A new ATS-3B is now (finally) on the air!!!

I had some trouble. I thought I would share, just in case anyone else is puzzled with the same issue(s).

After an evening or two, all was soldered. I cleaned the boards by soaking in denatured alcohol for a half hour or so, then scrubbed a bit with an old toothbrush. I then followed the calibration procedure. All checked out OK. This was back in July. I didn't get on the air with it right away. I still had to drill holes in the tin, etc. That required another week or two. (I'm WAY too busy!)

When all was tidy in the tin, no RX audio! That had me stumped for several weeks because I assumed that the calibration tone was OK during LO trim. (It worked before!) That caused me to look in the wrong area for the problem.

It ends up that I had two problems. C41 was open and the 4.9152 MHz BFO oscillator wasn't running. The latter was due to flux under the crystal. Evidently the residue provided just enough conductance to swamp out the oscillator. I cleaned the residue off with some acetone. Now finally the rig is up!!!

Note: Instead of using the solder that came with the kit I used whatever was laying around on the bench. I think the stuff I used has some pretty aggressive water soluble flux. The residue might have contained oxidation from the crystal can.

The experience was frustrating, but it forced me to understand the circuit theory.

The reward: The rig's maiden voyage was the last quarter of the NA CW Sprint. I worked thirteen different states throughout the country in about an hour using a random wire ~100' long and ~23' high, strung between a telephone pole and one corner of my house.

George and All,

My hearty congratulations George. It sure sounds like you considered the trip to be a complete success, and it strikes me as being so as well. The little ATS3 rigs are absolutely perfect for this kind of thing, and you certainly confirmed it. Hopefully this won't be the only time you get to make such an outing, and if conditions improve a bit you might log a bunch of contacts. Even so, as you say, the lack of sunspots hasn't made it impossible to make some interesting contacts. As empty as the bands seem to be these days, you just never know when a station will jump out at you, including some good DX. Anyway, I've been very impressed with my ATS3, and I love showing it off to others--especially the QRO guys!!!! They can't possibly be having as much fun as we are, can they???

When you leave home with out it! DOH!

Me and the boys went for a hike today. Not just any hike mind you. We were on a mission to tackle the NE face of Mt Herman (1800' at 45-60 degrees ...no trail, loose rock and brush and undergrowth to battle).

My motivation was 2-fold ...find a way to the top and once on top make a few QSOs with the ATS3a.

Well once on top and totally exhausted I sat and ate my PB&J sandwich while watching P&R nibble the vegetation. Refreshed I put an antenna and dug deep in the pack for the ATS3 ...no radio WHAT!!! ...Yikes!? I dumped the entire packs contents still no ATS! ...ARUGH! Dang I thought I packed it? I thought my packed seemed a little lighter (right! ...with the ATS you'd never know it's so lightweight)

I sat there feeling pretty stupid and imagining Rooster calling me a 'numb-skull' etc. I then pretend to call CQ and had few imaginary Qs. I took down the antenna and packed up and hiked down the mountain.

Sometimes the difference between reality and illusion is a fine line.

Must be my freq. counter since I tried listening on my receiver at 10 MHz and sure enough, there was the ATS-3b.
Moving on to the LO freq. trim step.....
I press menu and now get the "CO", but I don't hear any tone in the headphones. I do get audio annunciators, etc., just not that tone at this step in the checkout.
Help!

With a band filter in place I hear no difference in the audio noise level with an antenna hooked up.

Any suggestions?

Alan, NM5S

Allan

The lack of tone in the "CO" step sounds similar to a problem I had.
I hooked up an old transistor radio through a 3M ?? resistor to a pin
and worked backwards through the audio chain to find that the signal
dissappeared around U4.
Happened to have the earphones on while testing the voltages around
U4 and found there was a jump in noise when I pressed down on pin 1.
On REAL close inspection, noticed I had sat the solder on top of the
pin and not actually connected it to the pad. Easy fix ! Hope it
turns out to be a similar easy fix for you.

Good luck

Hi

Will there be a new edition of the The ATS-3B kit ?
Eventually a pcb would also be sufficial, it appears I have most of
the parts at home.Would really like to buy this cute tx.

Cheers

From: n8ewy
Topic: 3529 Message: 3529

I just finished my ATS 3-B. I have a long ways to go. I still haven't put power to it. I'm finishing up the band boards this weekend.

I have been looking extensively at the ATS/FCC-1 integration. That is my ultimate goal. When I was ordering parts such as the 2P2T switch and stand-offs and all I was confused by a couple things. I ordered from Digi-key. I got a good quality toggle switchand some of the other things. The only pushbutton "octal" type switch I found was made by a company named Cherry.. After looking at the picture for a long time, I got two of them and the two corresponding endcaps that allow you to clip into the hole you make in the box. The two switches each go from 0-7 (eight positions). I ganged the two together and with their endcaps on it appears much the same as the one in the file here in the group files.

Each swith has 5 connection points. One for a ground and four for connections from JP6 on the FCC-1.

My questions on this is: Is this set-up going to work? How do these switches work? I mean it makes sense to me that the five connections come from JP6 to the 5 connections on one of the switches. I'm wondering now if I got the wrong thing. How does the other switch and it's five connectors come into play? Did I screw up? I sort of understand the table on page 18 of the FCC-1 manual, but can someone help me visualize how this works with two switches with 5 connections each? If I do have the wrong thing and need to get the right "octal double pushbutton" switch, how does this work and get the right number of bands for the ATS?

Thank you and I hope this isn't too much to ask,

Thanks to all who suggested changing R12 to 1M. I did this mod to both my ATS-3A and ATS-3B today, and now sending is much easier on the ears. Riding the headphone volume control isn't a very practical way to deal with the excessive sidetone level in these rigs.

Unless your hearing is numb, you'll probably be glad once you remove R12 (marked 334, for 330K) and replace it with a 1 meg resistor. I used a 1/4W CF resistor surface mounted on the R12 pads - this works fine.

There are some artifacts in the audio related to the break-in T/R signals, and these are more apparent with the sidetone reduced - but they're much easier to tolerate than the piercing sidetone!

The sidetone was particularly loud when listening with sensitive in-ear phones at full gain - it's still strong with 1 meg for R12, but it's nice with the headphones turned down a little, as they normally are for QSO's with stronger signals.

NAQCC Sprint Wednesday night!
This coming Wednesday evening will be the monthly NAQCC Sprint for September, 2008.

I will refer you to the proper URL:

http://www.arm-tek.net/~yoel/sprint200809.html

There you will find all the details as to time, frequencies and also a special prize (a classic book in Morse on CD donated by Chuck Adams K7QO).

This month's Special Award goes to the winner of a drawing among the following: The one making the highest score in each division and having all ten digits (0-9) somewhere in the member numbers in their log.

This is a monthly event that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate (this includes QRO); but you must use QRP power levels to compete for awards.

If you do not already have a NAQCC member number, now is the time to sign up and get one. Lifetime membership is free and there is no obligation on your part. Just fill out the form on the NAQCC website and receive your membership number and certificate FREE!!

Come join us and have a real good time!

73 de Dave VA3RJ
NAQCC #0004

3532. ATS-3A Receive Audio

--- In AT_Sprint@yahoogroups.com, "k2qpn" <K2QPN@...> wrote:

Bob,

Congratulations on getting your ATS-3A going! The time you spend on your filter modules and alignment will pay off in nice performance.

I agree that the audio is a little raspy - I notice this mostly on weaker signals. Not sure what the cause is - it will take some serious work to understand.

Possibilities: U3a LM4808 has clipper diodes in the feedback loop. U5 AGC IC AN6123MS probably contributes to the sound of the audio. Audio AGC is generally imperfect. I haven't studied this IC yet. U4 74LVC1G3157 is a T/R switch for the audio path, but it might have some limits.

For some reason my ATS-3A sounds a little smoother than my ATS-3B.

Perhaps someone else has already done some research on the audio?

Many QRP rigs have audio problems. It's hard to understand how engineers can build such wonderful, complex equipment and let the audio stages degrade the signals. The FT-817 has a lot of hiss noise. Many rigs have distortion at low audio levels - crossover distortion, etc., due to compromises made with op amps.

Bob, be sure to try some other earphones - the ATS rigs seem to care about the headphone impedance. Headphones/earphones/earbuds vary considerably. Also be sure to use a solid power supply or battery - not an old half-dead 9V battery.

Note that the audio op amp IC U3a LM4808, as well as the rest of the audio chain, runs on regulated 5V - the same 5V line that feeds both SA612 mixers. There is a 100uF cap on the output of U9, 812C50, the 5V linear regulator, so we don't expect to see any problems due to audio ripple on the 5V supply. The regulator makes the audio chain of the rig relatively insensitive to power supply resistance.

The audio section of the ATS rigs does an amazing job of making loud audio with very little current draw and only a few tiny parts - making it really clean might be done by picking the signal off upstream and routing it out to an outboard audio amplifier.

Let's see if someone else has worked on this...

From: kc7fys
Topic: 3534 Message: 3534

I found 1M was a bit too much attenuation with my small RatShack
powered speaker--but just right for headphone situations. I paralleled
another 1M 1/8th leaded resistor and it wasn't right either--but after
clipping one side of it I realized that I could 'switch' it in or out.
So now with a toothpick or something, I can get two levels. Primitive,
but functional.

Hi Bob and Carey.

The ATS-3b transceiver is a design optimized for low current and low number of parts and it works very well taking the constraints in mind. The audio distortion may be created by following:

- First mixer is overloaded and creates all kind of images. The images are filtered out by the narrow IF filter and by the AF amplifier, which serves as an AF CW filter, but the audio left will have all kind of hisses superimposed. The overload could be avoided by a RX attenuator, preselector, sharp tuning antenna or all together. Milan OK1IF posted a mod for attenuator pot, which is very easy, effective and time proven.

- IF crystal ladder filter may be too narrow and makes each of the noise spike ringing. The crystal ladder filter is matched by 470||1500 ohms = 360 ohm resistive load, but the input is certainly not matched to the same impedance. Correct input matching to the same impedance 360 Ohm at 5MHz is 38pF shunt capacitor from pin 4 of the first mixer to ground (missing) and serial inductor 21uH, not 10uH. Not sure whether this mod will help to reduce ringing though. The filters are still a bit magic to me.

- Diodes are clipping at the first stage of LM4808. This certainly happens on very strong signals. On the other way if one removes the clipping diodes, Steve warned that the AVC chip will lock up for couple of seconds. Also if the AVC chip is overloaded, it will create severe distortion. I tried to understand from the AVC chip datasheet what is the maximum allowed amplitude, but I failed. The levels are defined in dBm and input impedance is defined, but I was not able to get any sense from it. Probably HF generator and step attenuator would help more. Anyway, the AVC chip has min amplification of 7dB and max amplification of 24dB, which makes only 17dB span of regulation, that is about 3S. If signal is weaker, it will be weaker in earphones. If it is louder, it will be distorted by AVC or clipped by the diodes.

- Output amplifier. I found out, that the audio power amplifier stage has too much gain and creates distortion. If you feed your TRX with a noise source, you will find one main peak and two smaller peaks 30dB below the main peak. The secondary peaks disappear if you lower voltage gain of the output amplifier to half. I found it incidentally when I implemented the volume control by digital pot. So if you have sensitive earphones, it makes sense to decrease AF stage gain instead of using in-line pot on earphone cable.

> I agree that the audio is a little raspy - I notice this mostly on
> weaker signals. Not sure what the cause is - it will take some
> serious work to understand.

This could be the effect of all but the clipping diodes. The clipping diodes act only on real strong signals

> For some reason my ATS-3A sounds a little smoother than my ATS-3B.

Isn't there a change in caps around the crystal filter? Maybe the filter in ATS-3b is sharper?

First of all I would recommend to add an antenna attenuator. Then to lower AF gain, probably by replacing R3 and R5 by 150kOhm or lower if one uses sensitive earphones and is using in line regulator on earphones already.

BTW I have finished the mod on my ATS-3b for variable IF bandwidth and switchable CW/SSB audio filter. Works well, but the firmware is still rudimentary. The IF bandwidth is regulated from 200Hz to about 1.2kHz (400-1600Hz) and I could switch off CW peaking audio filter off from the SW. The SSB reception is a bit difficult given the audio bandwidth, but it is possible. I will post pictures soon.

For me the QRP contact on Sunday while sitting at our lunch log overlooking Buffalo Peaks was truly a highlight of our trip and there were many! Admittedly, earlier in the day having my ATS3a 20m-CQ with only a 10' high dipole answered by a Alaskan station Doug/WL7CDC in Anchorage was heart stopping! But not as thrilling to catch Bruce/N7RR and Margaret/K7MWP in Yellow Aster Meadows in the Mount Baker Wilderness/WA.

At first I thought Bruce didn't hear my reply to his CQ. But was quickly rewarded with a QRZ?? My jumper-dipole antenna height was limited to only 10' due to the fact I grabbed the wrong feed line to take with ...but it still worked ok! Guessing maybe our 11,500' elevation helped some?

Honestly there's nothing 'sweeter' than making contact with kindred spirits while on similar wilderness adventures!

Bruce/N7RR writes:

From: Asfco
Topic: 3537 Message: 3537

I have never seen anything like this before. Perhaps someone out there could let me know the best way to handle this problem.
The stereo headphone jack on my ATS 3A has come off the p/c board. One of the pads actually came off the board and has left me with nothing more than a small square hole.where it once sat.
I am able to see what looks like a couple thin wires running crossways in the opening. I have the pad which was attached to the leg of the stereo jack..
What's the best fix for this? I am a bit hesitant to try soldering it back into that hole without seeking advice
I have never seen this happen..
Anyone?

> running crossways in the opening.

Sounds like it might be the remains of the pad. I'm not
aware of any via's on this board, other than the through
hole components.

> What's the best fix for this?

Clean up the damaged area on the PCB. If you're confident
the jack is still good you can re-use it, or install a new
one. Glue the jack down to the PCB with strong epoxy
(not crazy glue). After the glue is cured, use teflon
wire wrap wire to make connections from the connector leads
with missing pads to their nearest PCB trace, usually you
can just scrape a bit of soldermask away from the trace
that went to the missing pad and connect there. Put some
RTV or epoxy on the wires to secure them to the board.

> I am a bit hesitant to try soldering it back into that
> hole without seeking advice

The only holes associated with the connectors are for
alignment purposes, they don't have any electrical
function. The square pads are used for the connections
and aren't plated through.

1 photo=1000 words. If it's not a via, it's either
part of the pad or perhaps some of the laminating
adhesive.

> *** Jack is fine I would be very hgesitant to try
> what you are suggesting on the 3A

Why?

> I am refering to is the square hole left by the pad
> that has come off

Technically not a "hole" but "area". When you say "hole"
it implies a drilled or milled area that goes all the way
through the PWB.

I suggested the epoxy repair because with SMD parts
retention is accomplished by the solder fillet to the
PWB pads. There is no way to effect an adequately
strong bond of a repair pad back on the PWB, so you
need to secure the component to the PWB via a means
separate from it's terminations. If you wanted to
you could fabricate repair pads and solder the component
to them, obviating the need for jumper wires but you
still need to adequately bond the connector to the
PWB. I would consider removing the other connectors
and gluing them down as well as a preventative measure.

From: n8ewy
Topic: 3541 Message: 3541

I'm happiy as I can be. I did my smoke test and all was well. That is after I found an unsoldered side of an resistor. But all is well.

Can I use my MFJ 259B as a frequency counter to do the next step, "Reference oscillstor and frequency Calibration"? It has a frequency counter built in. It is a BNC connector. I'm pretty sure it's pretty accurate.

It says in the ATS manual, on page 23, at the bottom of the page, step 5, to connect the frequency counter to DDS Tp1. I assume that means to attach a piece of coax with BNC to the frq contr on the MFJ unit. Then how do I connect that to point TP1 on the circuit board? Do I solder a small piece of wire to stick up from TP1? Do I then connect the center wire of the coax to that wire sticking up from TP1? Do I connect the copper ground braid to anything? Then I assume I move the up/down switches until the frq cntr on the MFJ reads 10,000 Mhz. Is this sounding right????

Secondly ..... page 24 - "LO frq trim" ..... I don't have a scope so I will probably do as I have done in the past and connect a noise generator to the ant. Input and peak by ear the BFO cap. Sounding right?????

I'll have a couple more questions but this will get me started. Thank you in advance and I will await your response before I go poking around. It is working great so far.

Sincerely and thanks,
Dohn N8EWY

--- In AT_Sprint@yahoogroups.com, "n8ewy" <n8ewy@...> wrote:

Dohn,

Congratulations on getting your ATS rig going!

Using the MFJ-259B as a counter to set the calibration sounds like a good idea at first...until you ask how accurate is that counter? No counter can be more accurate than its time base oscillator. Is the MFJ-259B's oscillator any more accurate than the ATS-3B's oscillator? Unless we compare to a standard of some kind, we cannot answer this question truthfully.

If you can compare your MFJ-259B to WWV or a lab frequency standard, and verify the accuracy of your count - and determine a correction to apply - then your idea is practical. Otherwise you might degrade the accuracy of your ATS rig.

If you have access to a recently calibrated lab counter, you could check your MFJ-259B against it, perhaps using a crystal oscillator at 10.0000 Mhz, and determine the approximate error. ALL measurement equipment has errors. If you have a tunable crystal oscillator, you could zero beat it to WWV using a receiver, and then count your oscillator's frequency with your MFJ-259B, so you can determine the error. You could also observe the drift of the MFJ-259B as it warms up, etc. I have an MFJ-259B, but I have never checked its frequency accuracy, so I don't know how far off it is at 10.0000 MHz. Of course, every one if different anyhow. This is why we need standards like WWV, calibrated lab equipment, etc.

One of the pieces of homebrew gear I really need is a tunable crystal oscillator. This becomes a secondary standard for tests when zeroed to WWV. It would be very useful.

In the meantime I did something sly. I found a way to tune my ATS-3A below 30 meters to 10.0000 Mhz. I checked it against WWV and decided it was only a few Hz off - close enough for ham radio. Then I used the ATS-3A as a test oscillator to verify the accuracy of the counter in my HP 8443A tracking generator/counter. This device has an oven-stabilized reference oscillator, intended to be very accurate, but it hasn't been calibrated for years. I found that it was about 20 Hz off, + or - maybe 10 Hz or so, at 10.0000 Mhz. Very rough numbers, but good enough for ham radio. I used the counter to calibrate my ATS-3B, applying the correction as closely as I could. I think I did OK, but I went through the routine a bunch of times. I checked a lot of stuff I didn't list also. This is a real time-burner !!

Your ATS rig will probably be accurate enough for ham radio with no calibration. I'd suggest not calbrating it to any other device or counter unless you can actually VERIFY the accuracy of whatever you use as a frequency standard. This does NOT mean trusting the specs, thinking positively, believing it's perfect, guessing, or having a lot of faith. You can always come back and calibrate your radio later. It will not have fantastic accuracy even when calibrated, because of temperature effects, etc.

Has anyone out there measured the frequency drift of his ATS rig over temperature? I want to try this, because I have operated well below freezing with mine, and I plan to do that on future winter campouts. Right now I have no idea how much it changes frequency.

I know enough about frequency measurements to know that I am a ham radio operator, not a standards engineer! This is a serious subject, and it requires rigorous thinking and measurements. I have known a few of these engineers, and they are very special people! However, even with crude techniques and cheap tools you can get within 10 or 20 Hz as long as you can hear WWV at 10.0000 Mhz, and you can build or get hold of a stable oscillator to use as a comparison device.

On question 2 your idea seems OK - plenty of others have used noise sources or other techniques. There's plenty of information already on this site in these thousands of messages about how to do this many different ways. All you have to do is search with clever words, and you'll find many detailed messages from builders who tuned up their rigs last year or earlier. I used my scope and followed the manual, and so I recommend that you borrow a scope and do that. It seemed like a pretty good technique - I went through it several times.

I think every time you do the cal, you need to do the whole cal. It starts over when you enter cal mode. The old data is erased. The cal routine in this rig is actually quite cool and it enables the rig to be set up for better accuracy than most small rigs!

Good questions, and I hope others will chime in with better ideas and more insight. Striving for accuracy is a good thing, and it always leads to greater understanding of how our radios work.

Wish I had easier answers...

I would remove all 3 jacks and replace them with panel mount jacks like they use on the rockmite's. I love my ATS3B, but the jacks could be better. Even before you posted this, I had already planned on doing this to mine. I cringe every time I pull the power plug out.

Someone else already explained how to repair this. Scrape off some enamel from the broken trace and run wires to the panel mount jacks. Those will not give you any trouble. This should be a simple fix. GL.

I believe the opposite. The panel mount sockets are usually made of thinner brittle plastic. The SMD sockets used in ATS3b seems to be fine to me. I had a lot of problems with panel mount sockets. I had never any problem with PCB mount socket.

As a fix, panel mount jack may be a good way. Another possibility is to buy a through hole socket, drill the holes, make islands from the ground plane on the other side of the PCB and wire the newly created pads.

I mean use metal panel mount jacks like this:
http://www.flyaas.com/acatalog/JB-11HS.JPG
This type has a outer lock nut and will last forever and will make it easier to plug in and out without fear of ripping out the pads.

Maybe I wouldn't have needed to to do this if I had been able to get my jacks to protrude from the altoids tin. I got mine close, but they still won't stick through the tin.

I wonder if anyone has a ATS3B template in GIF of JPG format?

Dohn

I soldered a resistor wire clipping with a loop on the end for TP1 I also soldered a resistor wire clipping on the phone jack for another test point. Just make sure the leads are not very long - TP1 is very close to the band board and one's fingers.

I found that my MFJ 259 was not sensitive enough to detect the oscillator on the ATS II, III, III B or other transceivers - I have a low power rf amp that I attached. On the ATS 3B I first used the WWV method described by Mike but reverted to a Radio Shack counter with the WWV method - it was more than close enough. Final ATS accuracy was checked while transmitting at 2+ watts into a dummy load and then using
the MFJ 259 with a stub antenna (NOT attached to the ATS III). I also used another transceiver of known good calibration to check the
ATS transmit and receive frequencies.

Mike,

Please explain how to do this - for all of us - it isn't quite obvious - we need a few clues and details. Your method is superior because it eliminates the errors of other instruments.

1) Do you connect an antenna to the ATS rig and zero beat the signal that feeds through? Which band?

2) Or do you use coupling from the rig's oscillator to a receiver that's also listening to WWV? I think this must be the answer. How do you couple the signal from the ATS rig without loading the ATS oscillator - with a pickup loop, or just a wire positioned close by?

3) Do you just listen to the beats or do you use a scope to get closer? Please share your experience!

Thanks

From: radio_kx0r
Topic: 3517 Message: 3549

KX0R will attempt to operate from a campsite at 11,000 feet in the Indian Peaks Wilderness about 20 miles west of Boulder, CO, tomorrow night (Saturday evening your USA local time). I'll try to be on after 0200 UTC, 21 Sep UTC, weather permitting. This is 8 PM MDT Saturday evening, local time.

Hopefully I'll be running my ATS-3B, a BLT, and a dipole fed with ladder line. Look for me on 30M or 40M at first, near the ATS's default frequencies. After 0400 UTC (10 PM MDT Saturday night) I'll be on 40M if things are going OK. There's a chance of thunderstorms, so I may have to wait.

I'll try again Sunday morning, on 20M or 30M, weather permitting.

Maybe I can catch a few of you. I was at the site a week ago, and it looks great! On a little hill above a lake, with beautiful takeoff to the east.

72,

Carey

I got my ATS3B second hand as an untouched unopened kit (bags still sealed and in the original envelope so I know it is a "good un"). The date on Steves's envelope is 22nd Oct 07 so that should identify the batch,

The trimmer caps I've got are 9 off green top adjust and 4 off brown bottom adjust.

Ive obviously used one of the green top adjusts on the main board as that then leaves me with a "symetrical amount" for the filter boards, but which one on which board?.

Monunting the green ones upside down isnt a problem but can someone please give me a pointer as to which go where as I cannot see any other identification on them. (& apologies if this has already been covered on a Q&A I've missed).

As a seperate matter, has anyone (preferably in europe as this makes postage easier) knocked up any spare filter board blank PCB's.

I want to try out some of the other filter options and configurations (eg the 7.02M ceramic filter as I have one lying around and the other LC value filter options) however I prefer to do this on a copy and leave the original alone so I can easily go back to it (and run "side by side" tests to see which variant I prefer). If it aint broken dont fix it (fix another!).

I must say, this is the best put together kit I have ever come across. I initially wasnt looking forward to soldering that DDS chip but it turned out to be much less of a problem than I thought.

Hats off to you Steve. Many thanks.

If you got the manual on CD with the kit it should explain, but if I remember correctly the brown are for the 80 and 40 boards.

Sill me. Many thanks you are totally correct and the CD version identifies Brown for 40 & 80 and green for the other bands. I had forgotten that I'd printed the manual off the forum here. The CD version also suggests just clipping the caps to the "wrong" side of the board, aligning it, then swapping the caps to the right side to be soldered in but I'm more tempted to the "upsidedown" option so I can tweek again later

From: Larry Makoski W2LJ
Topic: 3554 Message: 3554

Hello everyone!

The Flying Pig's monthly "Run For the Bacon" QRP CW contest is tonight!

This friendly, low pressure, 2 hour sprint runs from 9:00 to 11:00 PM Eastern DST.

For all the details, please visit http://www.fpqrp.com/fpqrprun.php

The Flying Pigs QRP ARCI is now maintaining an archive of previous "pig-runs" for your viewing pleasure.

See you in the troughs!

Reminder from: AT_Sprint Yahoo! Group
http://groups.yahoo.com/group/AT_Sprint/cal

Run for the Bacon
Sunday September 21, 2008
6:00 pm - 8:00 pm
(This event repeats every month on the third Sunday.)
Location: Your shack or anywhere

Notes:
This Sunday evening, the Flying Pigs Amateur Radio Club International will be holding its monthly Run For The Bacon. This is a friendly, two hour QRP CW Sprint, which is open to ALL radio amateurs, will last from 9:00 - 11:00PM EDT (0200-0400 UTC Monday).

You may work stations once per band on 160, 80, 40, 20, 15 or 10 Meters. Suggested starting frequencies are 1.812, 3.562, 7.044, 14.062, 21.062, and 28.062 MHz.

The exchange is RST, S/P/C (State, Province, Country) and Flying Pigs membership number. If you're not a member of the Flying Pigs, and would like to be; then please cli

3556. It's alive! It needs calibratin'

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-09-22 09:18:11 UTC
From: n8ewy
Topic: 3556 Message: 3556

This is a copy of the email I sent to w1mt, requesting clarification on a couple of things from his calibration procedure. Things, that I'm sure you may all realize. I'm just sort of new at this. I'm absorbing as much as possible. Please feel free to discect this thing and reply group. Here it is:

Thank you for responding to my first email message so quickly. I'm ready to proceed with the "Calibration Procedure". I have a couple questions about it. Not because it is written poorly. I just don't understand things quickly enough. BUTT! I learn as I go! Thank you for your help this far.

Prestep - Peak which IF transformer? Which component? I have a noise generator. I have an "Elecraft N-Gen, wideband noise generator". With a double female BNC adaptor I can connect the N-Gen directly to my ATS 3-B. Does this sound right? N-Gen to ATS? Which component do I tweak for greatest "noise"? If it is CT1, I adjusted it and could not hear any change in noise level. If it is a toroid, is it just a matter of spacing the magnet wire?

Step #1 - I assume the trimmer cap is CT1. I set a marker line, up and down, on my spectrogram at 600 Hz. I was able to get movement out of the largest peak, graphically, on spectrogram, to where I placed the tip/point of the peak to rest on 600 Hz. Is this sounding right?????

Step #2 - Connect my K2, audio out, to spectrogram??? Tune my K2 to 10,000MHz????????? How does one "set the carrier" of WWV??? Where and from what rig should I see 606.8MHz?

Step #3 - Do I put the test wire connected to TP1 on or near anything specific to see this signal on Spectro????? Will it just be another "peak"??? So I still have my K2 connected to the computer with a fairly wide peak centered on the 600 Hz line I put on it?????????? Correct? And I'm now looking for another peak (being generated by the ATS board in CF mode) to move into the picture of Spectro. I'm gonna line these up? Superimpose them, as it were. How important is the 606.8 Hz number? Should I have set it in step #2 to 606.8Hz instead of 600 Hz carrier.

Step #4 - It says to move the up/down buttons to center the ATS rig's tone on the previously chosen frequency. At 600 Hz or 606.8Hz????

Thank you in advance for any help you can provide.

Dohn,

I have included some notes inline below:

--- On Mon, 9/22/08, n8ewy <n8ewy@...> wrote:

>
> Prestep - Peak which IF transformer? Which component?

This is only applicable to the ATS-3, NOT the 3A or 3B.

>
> Step #1 - I assume the trimmer cap is CT1. I set a marker
> line, up
> and down, on my spectrogram at 600 Hz. I was able to get

Correct.

>

> and from what rig should I see 606.8MHz?

The ATS rig sidetone is set to 606.8Hz by the firmware. Simply put the carrier of WWV on 606.8Hz. (For me, this puts my dial right near 10.000.000).

> How important is the 606.8 Hz number?

The idea here is to set the 10MHz output from part 1 of the calibration equal to the carrier signal from WWV. It's not critical that 606.8Hz be used here, as you just calibrating the ATS rig to WWV.

>
> Step #4 - It says to move the up/down buttons to center the
> ATS rig's
> tone on the previously chosen frequency. At 600 Hz or
> 606.8Hz????

I use 606Hz myself. Depends on how good your ear is as to whether you want to use 600 or 606.

Steve's tuning step during calibration is about 10Hz so you should be able to get within 5Hz during part 1 of the calibration. Part 2 (step 4) is setting the offset in the firmware to match the trimmer cap you set previously.

From: w9goc
Topic: 3529 Message: 3558

Dohn,
I don't have an FCC-1, so I am Not speaking from personal experience. Looking at the switch table you referenced on page 18 of the FCC-1 manual, it seems to me that you'd have an easier time with a single Cherry Hex switch instead of two octal switches. See the PAGA-3100 or CH687-ND and similar from Digi-Key.

I have another question on the FCC-1 truth table on page 18 - - why is the 15 meter position the same as the 'Dir' position? It would seem that 15 meters should be '0111' instead of the indicated '1111'

One person's opinion,

Frederick

Hiker safe with help of ham radio

By JACKSON HOLTZ

EVERETT, Wash. - A series of dots and dashes bouncing off the ionosphere Sunday helped save a hiker stranded on Buck Creek Pass east of Glacier Peak.

The hiker who broke his leg used a low-voltage portable radio and Morse code to send out a call to help.

Six hundred miles away in Bozeman, Mont., Robert Williams was testing his ham radio Sunday when he heard the call signal, "W-7-A-U."

Williams replied and quickly learned, in the dashes and dots, that he was talking with a 62-year-old Corvallis, Ore., man, who had slipped and hurt himself in the high Cascades of Western Washington.

"I just happened to be at the same frequency," Williams, 65, said Monday. "It's just a stroke of luck that turned out great."

Williams called 911 and was connected to Snohomish County search-and-rescue officials. He spent much of Sunday and Monday relaying information including GPS coordinates from the hiker to rescuers.

"It was quite an experience," Williams said. "I'm just glad that he was a ham radio operator and that I was able to talk to him. It made the difference for him."

On Sunday, rescue crews reached the man who had set up camp on Buck Creek Pass, at about 6,000 feet just west of the Chelan County line.

He was taken to safety Monday on horseback.

The call set in motion one of two mountain rescues Sunday.

A second team of rescuers went up Three Fingers Mountain after a man there fell about 200 feet on a glacier near the summit.

Including the weekend rescues, search-and-rescue teams this year have now responded to 100 missions, Snohomish County sheriff's Sgt. Danny Wikstrom said.

Both of the injured men in the past two rescues were well prepared for the wilderness conditions, he said.

"To have that equipment will save your life," he said.

The man on Three Fingers was hiking with three other people when he fell. His climbing party summoned help, officials said.

On Monday afternoon, he was taken by helicopter off the mountain to Providence Regional Medical Center Everett, sheriff's Lt. Rodney Rochon said.

He wasn't able to walk when he was loaded into the chopper, Rochon said. He apparently had sprained his ankle and knee in the fall.

Bad weather Sunday prevented helicopter rescues of both men. Teams spent a night in snow and frigid conditions in the mountains.

Rescuers on Three Fingers used a pulley system to hoist the man off the glacier and onto the trail, Wikstrom said.

Teams then carried the man to Goat Flats, where he was loaded onto the chopper.

Rescuers on horseback reached the man on Buck Creek Pass on Monday morning.

The trail from Darrington was washed out from recent storms and wasn't passable, so crews approached along the Trinity Trail near Lake Wenatchee, Wikstrom said.

It isn't the first time amateur radio operators have helped out with an emergency situation, said Allen Pitts, a spokesman for the American Radio Relay League based in Newington, Conn.

The radios work well when other kinds of communication fail, he said.

Ham radio operators were of paramount importance after Hurricane Katrina and when a tsunami ravaged southeast Asia.

Still, it's rare that Morse code is used to initiate a rescue, he said.

Amateur radio operators used to be required to know Morse code to get a license. That requirement was dropped a few years ago.

Since then, Morse code has actually gained popularity, Pitts said.

"Morse code will get through when no other type of communication will," Snohomish County Hams Club President Grant Hopper said.

Williams, the Montana man, said he was able to understand the injured man's code even when his signal became very weak. Voice communication over the airwaves likely would have become garbled or misunderstood.

The man had a low-voltage radio transmitter, which operates on about as much power as it takes to make a tiny Christmas tree light sparkle.

In the right conditions, radio signals can bounce off the Earth's atmosphere and ricochet thousands of miles.

"A signal like that can skip a long way around the world," Williams said. "You can talk to Europe or Asia given the right conditions."

This is the first time Williams has helped someone in danger using his radio.

The rescue likely wouldn't have been possible if the injured man weren't a competent radio operator, Williams said.

"My guess is that he was just waiting to hear from somebody," he said. "I happened to be the lucky one."

Hello together

I have a wrong DC voltage read out with the original firmware i get:
20-10

With the Firmware update i get 21r6.

The indication is the same no matter what the supply voltage is
(6 up to 14 volts).

I thanke you very much in advance for the support

Nice regards Rolf / HB9TSO

Rolf,

Is this a new problem with a previously working rig or is it first time problem?

I'll guess it's the first time and the likely problem is with R45/R46. Double check them.

3563. Get me outta this Alternative Key Mode!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-09-26 07:26:31 UTC
From: kc7fys
Topic: 3563 Message: 3563

Just kidding--but this has been happening to me... I know the answer is simple. With the W1MT firmware installed, what is the button that gets me out of alternative key mode? I have been forced by my own goofiness a couple times to power down mid-QSO when I accidentally got myself into that mode--and was unable to use the mode itself to finish out the QSO. Happened again just now. I'm getting into that mode by accident, perhaps because I often use M1 repeatedly, as opposed to using beacon mode and listening between CQs.
How do I get the rig out of this mode without recycling power?
Thanks,
Jonathan KC7FYS

3565. new morse trainer for Mac OS

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-09-26 20:10:40 UTC
From: john shadle
Topic: 3565 Message: 3565

Just wanted to give a heads up to those of you who use Mac OS (or know of folks who use Mac OS) about a new Morse Code learning device which is available for Mac OS.

This program is called the AD5RX Morse Trainer and it may be downloaded *free* from the Source Forge site:

http://sourceforge.net/projects/morsetrainer/

Jonathan Nall, AD5RX, is a ham who lives out in 6-land these days. By day he works in the tech biz doing hardware verification, but he really enjoys tinkering around with other things in his spare time. In this case, he's offering a G4FON-like program for Mac users. It has quite a bit of functionality of the G4FON program (QRM, QSB, effective speed and actual speed settings, etc.). In addition to those basic features, it offers the ability to set the number of stations QRMing and the ability of the program to read the code back to you (in English) to check your written (or typed) transcription.

The motivation behind developing this program (which he has poured many hours into) is to provide a quality, free Morse Code-learning program to Mac users who have been limited to pay-only or inferior programs in the past.

The program will always remain free, but since the program is still in its infancy he is requesting that Mac hams download it and try it out. Please email all comments to ad5rx@.... He is specifically looking for comments related to the UI and the speech function (mentioned above).

My interest in this is only that AD5RX is a friend of mine from college who happens to not subscribe to this list. That's all. I had nothing to do with the development of the program, personally.

3566. Construction question

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-09-27 01:04:41 UTC
From: n8ewy
Topic: 3566 Message: 3566

I completed my 3-B last week and did something a little stupid today. I wanted to change out my connector for TP1. I pulled the connector I had there and when I had cleared the hole with solder braid I noticed I had lifted the small circle around the hole and in the process lifted the trace a little in both directions. To R19 and in the other direction to U7.

The trace is still there connected to R19, but lifted off the board, not connected at TP1. In the direction of U7 the trace is still attached all the way to the through-hole at TP1.

I have repaired something simular to this on other projects with success, but this one makes me nervous .... I have alot of time and resources on this one. I am open and hope for some suggestions on how to fix this problem.

Anyone? Anyone? Please?

From: Stephen Wandling
Topic: 3565 Message: 3567

John,

Thanks for posting this. I have the G4FON software, but its on windoz
and while I have xp running on my iMac with Parallels, its cumbersome to
run it. I'm back into the hobby after a 50+ year break and my CW
copying ability is coming back, but I am sure it would benefit from
regular practice with a program such as this.

I installed the program, but it fails to open. The download from Source
Forge gives me a 1.9Mb dmg, and running that gives a 12.1Mb Disk image
that contains the .app file, but it doesn't run. I'm pretty surprised,
since application installations have been pretty bomb proof and this may
be the first failure I have had in the 2 years I've had the iMac.

I am copying AD5RX. Thanks Jonathan for bringing the G4FON idea to the Mac.

Thanks for the post John.

72,
Stephen

My 3B has worked very well for basically a year now--but today I was on 14.040 sending CQ from M1 and suddenly while transmitting the everything stopped. The LED indicated 8. (all segments lit). I was operating with a reliable 11.5V, but the SWR was just 1.8-1.9. (This I discovered after the problem happened; my feedline shifted or something and it raised the SWR.) Anyway... where should I start troubleshooting? Upon powerup it still shows all LED segments lit, no response from paddle or buttons. Same response with other band modules. Where to begin checking?

Hi Johnatan.

First of all, I would measure 5V and 3.5V stabilizers and the reset pin (7) of the controller. If 3.5V is still there and reset pin is high (1.5V or lower), then the PA FETs may be shortened.

If 3.5V is still there and reset pin is high (3.5V or so), then I would inspect the PCB for cracked joints, lifted IC legs etc. If that does not help, then you are probably in trouble and your controller may be in silicon heaven.

On W1MT's ats3Calibration.html file, the "Prestep" says to Peak the IF transformer for peak noise.

Is the IF transformer the same component as the "trimmer cap" referred to in Step 1, the very next thing after the "Prestep"?

I know the trimmer cap is the green trimmer at CT1. Doesn't seem like the "IF Transformer" and the "trimmer cap" could be the same thing. Otherwise you'd be adjusting for peak noise and then turn around and move that adjustment in Step 1 to shape the filter.

So what's the difference between the two (what component is the IF transformer?) and if they are the same thing, how can you adjust it twice?

Dohn N8EWY

Well ..... all has went well. EXCEPT: When I did the initial Reference Oscillator Freq. Cal, it went perfect. When I achieved 10,000MHz, I hit menu and the sidetone shifted to the low tone. However, I have done that process again a few times and when I hit the menu button it changes tones but not nearly as low. I'm guessing 600 Hz or more (not really that
experienced) but much higher than the first time I clicked menu and it was just as described in the manual.

I tried adjusting the up/down buttons and went back to 10,000 MHz and it still never shifted to the low tone like the first time I did the procedure.

Is this right? Is it important since it did it right the first time?

Vojtech,
Voltage on pin 7 of the controller is .87V. This is with the application of 9V and 3.49V and 5.01V out of the U9 and U10. (My VOM is an Akihabara cheepo, under 10$. But for these measurements it seems adequate.)
Am I correct then, that this indicates the strong possibility of blown 2N7000s?

> Voltage on pin 7 of the controller is .87V.

That means your device is kept in reset state. What voltage do you measure over R48? In RX state there shall be no current flowing into the finals so the voltage shall be zero. In that case the over current detector U12 shall be off and Q10 off also. If Q10 is on, then the over current detector is keeping your controller in reset state.

Just to verify this, you could try to remove R48 (0.1 ohm sense resistor) temporarily. If you blown the finals, at least the RX shall work when you disconnect the finals from the power supply.

In case the transceiver works now, then you need to solder wick the finals and replace them with fresh ones.

73, Vojtech

8.63V with 9V in.

#In RX state there shall be no current flowing into the finals so the
#voltage shall be zero.

It reads 5V at the gate. I had half a dozen of the 2N7000 mosfets
here, so I installed them just now. That's not a problem now.

#In that case the over current detector U12 shall be off and Q10 off
#also. If Q10 is on, then the over current detector is keeping your
#controller in reset state.

I'll go through and check voltages from Steve's chart. Is it possible,
as one other poster suggested--that I should simply re-install the
firmware? I am due for an upgrade anyway.
Thanks for your tips,
Jonathan KC7FYS

I did a few more checks on my 3B according to Steve's IC voltage Tables.

U1/U2 check out normally according to the IC Voltage tables on P26.
U5 also checks out.
U3 appears normal by the chart.
U4 has a single anomaly, OV on the P6 Control pin.
U6 is another story. Nearly every voltage is wrong.
1-0 (or .04)
2-4 OK
5, 6- 0V
7-.8V
8,9- .6V
10- 0V
11-18 .8V
19-20 .6V
21-23 .55V
24- 0
25-27 .05V
28- 0V

U7 is just as messed up as U6. Does this indicate a firmware corruption?

".8" is still lit on the LED. There is no audio output.
Hmm...

Dohn,

If I understand correctly, you are having the same problem that a few of us had with this portion of the calibration. What you have to do is do the calibration and then leave it as it is. Each time you go back to it you will find that the reference oscillator has reverted to the frequency before your first calibration. This doesn't mean that the reference oscillator was not still on the correct frequency after your first calibration, but rather that the process of checking the reference oscillator again always resets its frequency to some initial frequency.

Hope this help.

Stephen,

Thanks for the response. So what you're saying is leave it alone? Move on to the next step? That was my initial thought. It went so smooth the first time. On that subject:

I have a decent volt/ohm meter, a bench frequency counter, spectroscope and a RF probe to get the job done. It looks like there isn't much I can do in the "Local Oscillator frequency trim" on page 24 without an O'scope. I peaked CT1 using spectroscope with a marker at 600Hz. I guess what I did was center the filter shape on 600 Hz. Is that the same as what it said to do in the manual? "Adjust the green BFO trimmer cap, Ct1, and peak the audio signal at the headphone jack"?

Have I missed anything as far as calibration goes, considering the equipment I have? If not, then I guess I can move on to Band filter adjustments right?

Dohn,

If you are using the small 9 V battery such as those used in a smoke
detector, it appears that they are unsuitable for this rig. I did make
a couple of contacts with one, but they are not recommended.

I am wondering why you are trying to get the power below 3 watts? What
are you using to measure your power output? What power out are you reading?

I was going according to the adjustments called for on Pg 24 of the 3-B manual. I'm pretty darned happy. I am using a newer MFJ-872 SWR/Watt meter set to the 5 watt range. I have all of the band boards right there between 2.5 and 3.0 watts with a 9.0 volt battery. I don't have a good bench power supply yet. Next on list. I just kept a fresh Energizer all the way through this process.

Most of the boards didn't need much in the line of adjustment all the way through. Once I've got her completed I'm planning on going back and change out some caps and stuff to squeeze some more out of her. I'm just not that experienced yet. With the lack of test equipment, my hands are a bit tied. I have a great feeling about this rig so far.

My K2 and K1 taught me a lot and I've been able to put that small bit of knowledge to use. I can't tell you how much it means that you have replied. I haven't had a great deal of reinforcement this project. I'd give my left leg for a mentor in my area for some help in theory and test equipment usage. I catch on quickly, but I have to sort of see it once to absorb and gain good understanding.

I'm on my way out in about an hour or so to see the "Gibson Brothers", a very good banjo and string combo in a small excellent venue. There are just a couple other things as important as getting a handle on this love of QRP I've got.

I haven't put any effort into tuning my modules because I do not yet have my 'optimum' battery pack. Knowing that the rig does not do well over 12 V, I may just end up with an 11.1 V LiPo pack. My concern was peaking the filters on a low voltage and then doing damage when I started using my higher voltage source. It may not be a realistic concern, but its mine!

I have to admit that the G4FON type software does not provide 800 wpm
code to be copied. After listening to PARIS at 100 wpm I can see why.
I suspect solid copying of 25 or 30 wpm would satisfy many, if not most,
hams.

I'll do that today. The rig was sitting on my bench transmitting into a poor SWR when it happened--so I'm suspecting that the guy who said my firmware was zapped by stray RF. I'm going to upload the new W1MT firmware this morning. See if that works.
Thanks for the tip.

Jonathan,

Because the RST/ (reset NOT, active low) is always low and VCC appears to be normal, you should probably look at Q10 , R49 and U12. RST NOT always low explains most of the other measurements you listed, including U7 and U4.

I tried to find specs for U12 but have failed - it appears to be some sort of over-current protection -

if Q10 is always conducting then RST NOT will always be low. Maybe Q10 has a short between Collector and Emitter - doubt that the MPU has been injured nor the Flash Memory.

Best of luck

Hi Johnatan.

To which version of the schematic do you refer? I looked into the files posted to AT_spring group and I did not find any U4 and U6.

The chip basically translates voltage over the sense resistor to a current to ground.
Iout = Vsense * 10000

On p26 of the Sept 10, 2007 version of the instructions, I have a chart labeled IC Voltage Tables with some values written. "U6 MPS430 MPU" and "U4 Analog SPDT Switch" are the two I am referring to.
Thanks for your comments, Vojtech. I'm still poking around and measuring to find the problem with this board. It happened without any mechanical bump or impact--during XMT, so it's probably related to that part of the rig.

I'm guessing this is a known issue--is Q10 mis-printed on the PCB as Q5? I'm suspecting that's the one by where it is.
What voltages should I see on Q10? How's this one checked? Do I desolder it to do so?

Hi Johnatan.

If the pin 7 (reset) of MSP430 controller is kept down by over current protect circuit, than it is perfectly OK that the DDS control lines and analog switch control line read different voltages than they should be.

You told me that:
5V and 3.5V stabilizers are OK
Controller is in reset state.
Pin 24 of the controller is at 0V. This pin is controlling the finals, therefore the finals shall not be powered.
Voltage over R48 (over current sense resistor) is 8.63V with 9V in.

The reset state may be caused by messed up firmware, but it may be a hardware problem as well. The voltage over R48 you indicate is very high. The resistor R48 has resistance 0.1Ohm. Voltage of 8.64V divided by 0.1 Ohm indicates 86.4A! This is not feasible. You either did not measure voltage across R48, or R48 is not soldered correctly. The voltage accross R48 shall read zero if in RX mode and 0.05V if in TX mode and 0.5A is flowing into finals. Would you please read voltage across R48?

Is any of the transistors hot (Q5, Q7-Q9), if you connect the battery? Would you measure current flowing into your TRX?

Just to be explicit about what I'm doing here. VOM set on 200m I get a
reading of 62.5mA current draw in RX. (I call it RX, but I don't
actually know WHAT state the rig is in, as I see only the "8." on the
LED and no audio hiss or output that I can see.

Jonathan,

I now have the lastest schematic,, "Rev. 1 9/15/07" which identifies what I was calling Q10 as Q5 (consistent with the parts list, Blue MMBT2222), and the transistor labeled Q5 is now labeled Q6, giving a total of 9 transistors.

I think the problem is not in the firmware but either in U11, U12, or Q5, or even possibly in Q6.

The voltage on the base of Q5 should be less than 0.6 VDC or Q5 will conduct and drop the voltage on pin 7 (RST_NOT) of U6 and hold the MPU in reset.

As Voljtek mentioned you need to measure the voltage across R48 which should be VERY low as Q6 should be cutoff and there should be a very low current. Look also at the voltage on the drain of Q6 which should be
zero since it should be cut-off. If it's not close to zero then it must be shorted between the source and drain.

If Q6 is OK then the problem has to be very close to U12 or Q5. If not in U12 or Q5 then it must be U11.

all the best,

Grant

Voltage across R48 is 0.0.
I was not measuring it ACROSS the resistor R48. Voltage from either side of the resistor to ground.

What should I see on each tab of U12?

voltages on pins 1,2 should be V+, and probably zero on pin 3

can you see any voltage on the base of Q5?

No voltage on the base of Q5. .79V on the collector and emitter of
that one.

Q6 shows:
7.9V on the Gate
0V on the Drain
8.7V on the Source

Jonathan

Voltages sound good on Q6 - I was wrong - the Gate should have a positive voltage as Q4 is shut-off.

And the Q5 collector and base sound good, but the voltage should be zero on the emitter as it's tied directly to ground...

check the emitter again.

starting to sound like U11 is a suspect

by the way just saw your youtube touch keyer video - where can one find the specs/directions on building the touch keyer?

That's what I'll do now. I'm also gearing up to reload the firmware. I don't think it'll hurt to take that variable out of the mix here.

> by the way just saw your youtube touch keyer video - where can one find the
> specs/directions on building the touch keyer?

Grant, I'm between kit-building and actual homebrewing of my own projects and ideas. Very much closer to being just a kit builder, however--and as such, I am 'emerging' in my knowledge of what's going on in the circuits I solder together. So, all this troubleshooting is a classroom experience for me.

About the touchkeyer--I'm proud of that installation (and the video, which got hundreds of views in all kinds of countries), because it works! I do not deserve any credit, however, for anything more than soldering together the KIT. He he. I fall somewhere between the craftsy "Make Magazine" bunch, and the "EMRFD" crew. I do, by the way, OWN Experimental Methods, but am still reading Frank W. Harris, KØIYE's "Crystal Sets To Sideband." I'm trying to fill in all the fundamentals that I lack as I do actual soldering and troubleshooting that's over my head.

On this ATS list, I am very much a 'junior' member in terms of engineering knowledge. Still, this kind of troubleshooting benefits me a lot. In the background I'm Wiki'ing all the components, looking at data sheets just to see which each tab is--all that basic stuff.

Back to the matter at hand. Emitter on Q5. Stand by.

It's also 0.0V.
Again, there is 0 on the base and .79V on the collector with what
measures as 9.02V in.
I'm going to flash the firmware now. I have an old Win98 machine that
I have to crank up to do that, and it's never quite like the
instructions say it's supposed to be.

Hi Johnatan.

Your controller is kept in reset state and it does not seem to me that flashing the chip will change your situation. The pin 7 of MSP430 is reset input only pin and is kept at 0.8V by external circuit.

If Q5's base is tied to ground, than Q5 (MMBT2222) is supposed to be closed and is most probably not causing the reset state.

It is very hard to guess now what is wrong with your device. The pin 7 of MSP430 shall be pulled high by the reset supervisor chip U11 and may be pulled low by Q5 if current flowing into finals is too high. If it is pulled down by controller, then the controller is faulty.

At this point of time I could only recommend you to desolder parts that may keep reset (pin 7 of MSP430) low. That may be U11 (MCP120T-3151) or Q5 (MMBT2222). After you desolder U11, R43 will still pull reset pin high. If you still measure pin 7 low, then you may desolder Q5. If the pin 7 of MSP430 is still low, then the controller is most probably dead.

A piece of advice how to desolder a part. It works for me to instead of sucking the solder away to actually add an abundance of solder over all pads of the parts. After all pads of a part are melted, I just push the part away with the tip of soldering iron. The capillar action is keeping the solder blob with the part on the tip. Then just shake off the part on the table and remove the solder from it. Use solder wick to clean the board.

Also you may not be able to change the firmware while pin 7/MPU is held low - I noticed that it's involved with the external programmer connector

Vojtech and others who've given advice,
I desoldered U11 first--no change to .8V on Pin 7 of U6.
I then desoldered Q5--again virtually no change to Pin 7's voltage. (.75V).

What would the obvious things to check before concluding I've damaged the MPU U6? Although spontaneous solder joint failure is less likely I've given the board the once-over; inspected the board itself, connections, components physically. Somebody mentioned the switches, which appear to work as usual. I've checked and re-checked that the input voltage is 9V +/- a percent or so. (Alinco DV 33MV power supply, and an AA battery pack used alternately). I've gone over Steve's voltages chart in the manual and found the MPU to be off--or as interpreted by Vojtech to be in RESET state.

All LED segments are still lit with no hiss or signal from the audio output.

I removed my touchkeyer unit just to make sure there was no possible interaction that might be causing this.

I used hot air, which I find easiest for removing components. I fashioned a heat-focussing nozzle from a kitchen funnel and some kung-fu with a Dremel.
http://www.flickr.com/photos/jonathancharles/2900740972/

Before I seek replacement of U6, what should I check? It always seems to be something extremely obvious--but in this case, it appears to be an actual component failure from my transmitting into a not-ideal SWR with 12VDC.

I am unable to flash the firmware, either.

DOA?
Thanks,
Jonathan KC7FYS

Jonathan,

If it were my rig, I would touch lots of connections with my soldering iron. It is my experience that visual inspection can be misleading. While I have read the posted suggestions and theories, it is not intuitive that an SWR mismatch might damage the MPU, but you must remember that I speak from a position of significant ignorance.

Good luck

Topic: 3611 Message: 3613

Jonathan,

check the value of R43 which should be 47K and check the connection on the InCircuit programming connector - in particular, measure the resistance to ground of the connector pin connected to U6/pin 7 - should be very high.

U11 has an "open drain" output and won't pull up pin 7, R43 is supposed to pull up the voltage on pin 7 - this could be the problem if it's open.

Can't see any other paths to ground

If these fail then probably U6 is smoked, or there's a solder bridge somewhere

Let us know how these turn out

72 Grant.

>
> What would the obvious things to check before concluding I've damaged the MPU U6? Although spontaneous solder joint failure is less likely I've given the board the once-over;
inspected the board itself, connections, components physically. Somebody mentioned the switches, which appear to work as usual. I've checked and re-checked that the input voltage is 9V +/- a percent or so. (Alinco DV 33MV power supply, and an AA battery pack used alternately). I've gone over Steve's voltages chart in the manual and found the MPU to be off--or as interpreted by Vojtech to be in RESET state.

Hi Jonathan,

Did you measure the resistance across R43? best way is to measure would be from the input pin (2) of U11 to pin 7 of U6 - should see 47 K ohms. Also, check the resistance from pin 7/U6 to ground - should be pretty high. Since neither U11 nor Q5 have any influence on pin 7 voltage there's got to be a low impedance to ground or R43 isn't passing any current.

You've built quite a few projects - I'm impressed. I retired after 35 years as an engineer with a lot of experience in software development and digital logic design. Even though I took a lot of physics and electrical engineering classes in college, most of what I learned about electronics was actually from involvement with HAM radio! Trouble shooting problems like this are really the most fun, once you've found and fixed them - nothing like it! Keep up the good work

From: Vojtěch Bubník
Topic: 3611 Message: 3617

I back Grant's comments.

Only one word of caution. If you measure resistance of the CPU IO pins against ground or Vcc, you will find out there is a reverse polarized diode inside the chip between each IO pin and ground and another reverse polarized diode between Vcc(3.5V) and IO pin. Therefore if you measure resistance from IO pin against ground and put the + electrode of your DVM to GND, then you will measure resistance of theinternal diode and the diode will be open. The same applies to measuring R43. If you connect the - electrode of your DVM to 3.5V and + electrode to IO pin, then you will measure resistance of the internal diode. If you want to measure resistance of IO pin against ground, connect - electrode to GND. If you want to measure R43, connect - electrode to pin 7 of the controller.

Hope it makes sense.
73, Vojtech

Dohn,

I have a QBSA which is still in the original package and I don't think I will have time to get at it anytime soon.

The only trouble is I'm headed out of town tonight and won't be home until the 10th of Oct. If you are still looking and are interested please drop me an email.

> Hope it makes sense.

Thanks, Grant and Vojtìch,
R43, by that method shows a reading of 47K on my cheap VOM.
I went over and touched up solder joints that I could with my
fine-tipped iron. I also replaced U11 and Q5 with hot air, which
worked pretty well.

Shorting across R43 gives me 3V at pin 7.

Perhaps this is useless information, but the InCircuit Programming
Connector resistances to ground are:
1-0 ohms
2- 112 ohms
3- infinity
4-7 45 ohms

I gave the board a thorough cleaning with YaniClean, a Japanese
defluxer spray. I also gave it a gentle twist as per Steve's tip in
the manual. The only consistent thing has been the ".8" on the
display. If I had spare parts I could have easily swapped them out
one-by-one by now. Desoldering and resoldering has been a snap with
hot air so far.

Looks like it's time to watch me some TV!

A basic question about the U6 MPU and the formative process: is it
programmed, then the firmware flashed after that? Or is the firmware
the only changeable part of the chip's function? So, if I were to get
that same chip--and it turns out that it's indeed my problem, could I
swap them and then be able to load up the firmware and um... be in
business?

I'm guessing that's not the case, and Steve does initial programming
of U6.

The voice of a troubleshooter at the end of the line is always so
pitiful. No paper is quite light enough to be held down by the
ATS3--so it makes a lousy paperweight; what are the options?
Thanks for your guidance,
Jonathan KC7FYS

You should be able to replace the chip and then flash it in circuit. Doesn't have to be flashed before putting it in circuit.

This problem has been very intriguing and unusual ...

Then it'll be fun to swap them out and see if indeed that does it. I had the rig on beacon mode, and was listening between CQs for a responder. It had been running about 5-10 minutes into a load that I didn't realize was 1.8-1.9:1 SWR. The ground is very poor here, too, on the 4th floor. I don't know if there was enough stray RF or whatever that might have caused this--but the likelihood of solder bridges, intermittents, broken parts--is all extremely low given that the rig has been in the field and on the road and kind of 'broken in' gently. It was just sitting there untouched when it stopped workin' and lit up ".8"

Beats me.
Jonathan KC7FYS

PS. The instructions for the firmware update don't usually match my actual experience using the program. Usually it's around the end when I get "hardware not found" errors and have to do multiple restarts and eventually something works right and it is loaded. Next time I flash the firmware in, I'll notate these more specifically. (Using Win98)

3627. Ultimatic vs. Iambic Keying

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-02 11:43:20 UTC
From: k5jfp
Topic: 3627 Message: 3627

I'm a newbie here ☐ just recently got my ATS3B going ☐ still tweaking. I am old school in CW keying, and can send great CW up to probably 50 wpm with my trusty single-action paddle and Ultimatic keying. Put me in front of a modern dual-action (squeeze) paddle with Iambic keying and I am a total lid. Has anyone considered an option for Ultimatic keying in the ATS3B? That would sure make life easier for me, since the paddle I now use is dual-action (the Palm mini).

Thanks,

Gary W5ZL

3628. NAQCC Special Event Station N3A

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-02 14:33:00 UTC
From: NAQCC
Topic: 3628 Message: 3628

We invite all ops to come help the North American QRP CW Club (NAQCC) celebrate its Fourth Anniversary.

How?

By working our special event station N3A which will be active during the whole month of October.

A handsome certificate and/or QSL card is available to everyone who works N3A and requests one or both.

We also have 3 special certificates for the FISTS members who make the most different band QSO's with our N3A stations during the month and in the FISTS and NAQCC sprints.

N3A will be operated from all 10 US call areas with the appropriate portable designator - N3A/1, N3A/2....N3A/0.

All 10 calls will be active in the FISTS sprint on the 11th and our NAQCC sprint on the 14th (15th UTC).

Full details including an operating schedule and how to request the certificate and QSL are on the "N3A Operation" page on the club web site - search "NAQCC" in your favorite search engine, or follow this link to our website (www.arm-tek.net/~yoel/main_n3a.html).

Join us in celebrating our Fourth Anniversary, share the fun and earn a few certificates and special QSLs!

This is also a good opportunity to join NAQCC. Lifetime membership is free and you will receive your membership number, membership certificate and starter kit FREE! No cost or obligation on your part.

73,
Tom, WY3H (NAQCC President)
John, K3WWP (NAQCC VP)

3629. still stumped - no low pitched tone during ref. osc. freq. cal

Date: 2008-10-07 03:22:29 UTC
From: Alan Shapiro
Topic: 3629 Message: 3629

I still haven't found the culprit. In the check out and cal for my ATS-3b all steps OK until #8. I get the "CO" in the headphones, but then no "low pitched tone".
I noticed that I can inject audio into pin 3 of U3, so it seems the audio is OK. I've checked all the IC voltages and all is pretty close. Any ideas?

thanks!
Alan, NM5S

Hmmm. The fact that you get the 10MHz at TP1 tells me that the DDS is working.

While in CO mode, try tracing the signal from C34 into the first mixer, then out the first mixer, through the crystal filter and in/out the second mixer. The freq into the first mixer through the crystal filter is nominally 4.9147 MHz. When that signal is mixed in the second mixer (with the 4.9152 crystal X5) you should get something under 600Hz out the 2nd mixer. If you can use a scope to see if you have signal at the proper places you might be able to isolate where the problem lies.

I may have missed something, this is off the top of my head, so if anyone sees anything else chime in.

Keep us posted.

Topic: 3629 Message: 3631

This same thing happened to me I think. The very first time I went through the calibration everything worked perfect. I got the low pitched tone. But from that time forward, I could not get the low pitched tone after I did everything else. I continued one and sort of finished up and the rig seems to work great.

I'm not real experienced in theory. I did get a reply back then (maybe three weeks ago) which I can't find. It made sense though. It bothered me, but as I said, I think the rig is working OK with the exception that I can't get that low tone during that routine.

Hmmm. The fact that you get the 10MHz at TP1 tells me that the DDS is working.

While in CO mode, try tracing the signal from C34 into the first mixer, then out the first mixer, through the crystal filter and in/out the second mixer. The freq into the first mixer through the crystal filter is nominally 4.9147 MHz. When that signal is mixed in the second mixer (with the 4.9152 crystal X5) you should get something under 600Hz out the 2nd mixer. If you can use a scope to see if you have signal at the proper places you might be able to isolate where the problem lies.

Hi All

I just don't have the time to build my ATS-3b and I would rather someone else could enjoy it.

I will happily sell it for what I paid - $200 (or equivalent) plus shipping costs to wherever you are (Note: I am in the UK).

Please reply directly to me if interested.

I was thinking that too. The soldering with solder paste and hot air tools goes quite fast, but the coil winding takes some time. Some debugging is also usually needed. Anyway needs a few evenings after work - time that could also be used for something else.

Quick time estimate. One evening is about 4 hours of work without breaks.

1. evening all passive SMD components

2. evening all SMD semiconductors and small DDS chip

3. evening all through hole parts

4. evening all filter boards without coils

For coil winding I would guess that 6 toroids for two boards needs one or two evenings.

Mike,

To be specific: I hear 10 MHz in my receiver. I do not see 10 MHz either on my scope or on my freq. counter. In the "CO" mode I looked for DDS LO with my scope and find a signal of approx. 8.6 MHz rather than the 4.9147 MHz. Does this problem send me to the MPU?

Probably cogent to anyone installing or updating firmware. I'm having this issue. Windows 98. One step in the IAR Embedded Workbench IDE program. LP1/LP2/LP3 are three choices in one step of the firmware flash process. I need a brief rundown of what that is. My PC isn't "seeing" the physically connected processor. Where else may I see where this connection is--aside from inside the IAR program itself?

Hello all,

I have written to the group several times and received great advice and assistance. I live in the Tecumseh, MI area, just south of Ann Arbor. I am looking for someone who might be willing to meet with me, face to face, for some assistance using an oscilloscope and with some tips and/or theory in trouble shooting.

I have built several rigs with very good results. I have since rendered them useless, in two cases (a NC 40A and a SW-40), on transmission.
Probably the finals, but that is a very uneducated guess. I have a good Extech volt/ohm meter and a new bench grade frequency counter. I also have a variety of noise generator and other small Elecraft type bench helpers. I am thinking seriously of getting an oscilloscope sometime soon. I will not do it though until I am confident that I understand its usage and the theory necessary to apply it. Unfortunately, I can only learn so much googling and yahooing. I usually learn more in 5 minutes, hands on, than I can figure out in a day searching the internet.

Sooooooooo ..... I was hoping against hope that I might find someone within a reasonable driving distance willing to meet with me and just go over a couple of these things. Perhaps help me understand some basic theory involved with construction, component uses and differences and subsequently, <frown>, troubleshooting .

Once again ..... I am in SE Michigan. Tecumseh actually. I am driven in this endeavor and willing to travel some ways to accomplish it or assist someone to reach me.

Please contact me privately. This is slightly embarrassing. <grin>

Thank you for the bandwidth and I hope to hear from someone.

NAQCC Sprint Tuesday night!
This coming Tuesday evening will be the monthly NAQCC Sprint for October, 2008.

I will refer you to the proper URL:

http://www.arm-tek.net/~yoel/sprint200810.html

There you will find all the details as to time, frequencies and also a special prize.

This month's Special Award goes to the winner of a drawing among the following: Those working the most different special event calls (N3A/#) in each of our 5 sprint divisions.

This is a monthly event that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate (this includes QRO); but you must use QRP power levels to compete for awards.

Come join us and have a real good time!

Hi Jonathan,

Have you measured the resistance/voltage on pin 7/MPU, the RESET?

If it's still low then we have to find the cause before you can reload the firmware.

maybe we can find it where you are with your present resources.

Grant

Yeah. One thing about this device-parts are so cheap compared to time spent uninstalling and reinstalling. If I could discover the problem by 1-by-1 replacement and testing... A kit of the 15 most likely to go belly-up components would be handy.
Jonathan

It's usually not the parts fault, but the act of installation or stress
on connections that causes failures.

I have heard of Ultimatic Keying, but until now never took the time to research what is was, sounds interesting. I see that my N0XAS PicoKeyer supports this mode. Since I have not done too much with Iambic for it to be a preferred mode, I think I will give Ultimatic it a try. Maybe the 3B firmware can be changed at some point to include this mode.

The K1EL keyers have ultimatic mode. I have a K40 ..

http://k1el.tripod.com/

FWIW,

I never knew how bent I was on needing Iambic mode B until I tried using the ats3 iambic mode A.

My sending (in mode A and even the previously broken mode B) was such an embarrassment that I hardly ever used the ATS3 on the air.

I recently went into the firmware and made sure I never accidentally ever select mode A again.

From: qwasty
Topic: 3627 Message: 3657

I have some research to report.

George Carey Fuller, KX0R, recommended the Palm Radio Mini Paddle in his eham.net review of the Elecraft KX1. It looks like the ideal portable CW key.

http://www.eham.net/reviews/detail/3586?page=2
http://www.mtechnologies.com/palm/

I noticed that Palm Radio Code Cube is a tiny keyer that plugs into the back of the Mini Paddle.

http://www.mtechnologies.com/palm/cc.htm

The product webpage does not mention what keying modes it can do, but it does mention that it uses a Jackson Harbor Press PK4 keyer chip. Further research showed that the Jackson Harbor chip is actually the latest PK-4 SSR chip, and, here's the best part, the chip does Ultimatic keying.

http://home.att.net/~jacksonharbor/pk4ssr.htm

So, you got your hardy little Palm Radio Mini Paddle with the optional Code Cube, and you have Ultimatic mode keying in a tiny rugged package, ideally suited to portable or backpack use with the KD1JV ATS-3B QRP radio. So, it looks like this problem is solved. All that's left to do is try it.

The mini paddle is an excellent paddle (I own one and love it) but the ATS3 rig is a gram counters dream radio.. It's a real bulls eye for backpacking unless you need to haul around ton of accessories with it. That is why I (and several others) use integrated home made touch paddles.

That's an amazing photo. How did you operate the camera with one hand on the radio and the other on the touch paddles? Surely that's a superior setup to any commercial solution.

I've been out of the hobby for many years, but maybe I'll be getting back into it soon. If I do, I want that...that thing...in the photo. I'll need to start by getting a soldering iron I guess.

You have any details on how you put the touch paddles and keyer together in your neat integrated package?

Ha-ha
You know, I did play around trying to get a good shot but I cant remember exactly how I did it.. I am sure the camera was strapped around my neck.. I will have to look on my hard drive for clues.
There are some better integrated paddles designs than mine. The best that I have seen is an AC plug that is integrated beautifully into the front of the altoids tin. Another is a guitar pick on the top. I cant remember all of them but they all looked a ton better than mine.

Here is a photo of the home made paddle before it was glued to the bottom of the tin..

3661. Touch Keyer

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-15 04:35:21 UTC
From: kc7fys
Topic: 3661 Message: 3661

And there's mine--which is somewhat of a copy of Ken's nice design.
<http://jp.youtube.com/watch?v=yqnt2zUpJcw>
or photos
<http://www.flickr.com/photos/jonathancharles/2291295848/>
I still prefer external paddles, but I have saved a few QSOs when
something wasn't right with the paddles by hitting the touchkeyer.

wrote:

Ken,

Do you think there are problems in the ATS3 (or ATS-3B, etc) Mode A
programming?

I'm one of those people that can't deal with Mode B. I've tried it
with other keyers and I don't like it. I just don't get it or see
the point. I would rather use single lever than fight with Mode B.

But, I've noticed that the Mode A on the ATS-3A and ATS-3B seems a
little rough in some way, but I can't put my finger on it. I just
seem to make more timing errors and get extra dits, stuff like that.
I have a hard time using the iambic squeeze feature without getting
an additional dit or dah, etc. I often end up sending without
squeezing both levers, in effect, single lever sending, to avoid
errors.

Is this me, or is there something slightly off in the way the keying
is timed or programmed? I don't go very fast - 20 WPM average. I
know there was/is a problem with Mode B.

I think my CMOS 4 keyer sends easier in Mode A, and even my TICK 4
and K10 keyers seem better - whatever it is must be subtle.

I like the idea of using an external keyer like the PALM - we also
could probably wire a TICK or a K10 into the box, silly as that
seems. Any experts out there?

Thanks

Carey

Well..
I cut my teeth on the old bencher with a built in MFJ keyer.. maybe that's what messed me up so bad.
Mode A was never my strong mode but I never had an absolute intolerance for it until I built the ATS3.. I think my CQ turns into NQ or something like that.
For a while, I had huge problems even with mode B on the ATS3. The W1MT firmware seems to have made a big difference in the mode B so I really have no issues with it any more (thanks Mike!).

My Sierra and my K2 built in keyer are no problem for me.

The CMOS-4 has been a long time favorite keyer for my home station equipment that needs it except for its pathetic raspy side tone (which I turn off anyways).. My MFJ-459 keyer has a very nice side tone and it keys nicely but it is has a bunch of engineering goofs that counter its asking price of $179. If you are interested you can see my review at http://www.eham.net/reviews/detail/3763 (just look for AA7JC).

Ken,

Do you think there are problems in the ATS3 (or ATS-3B, etc) Mode A programming?

I'm one of those people that can't deal with Mode B. I've tried it with other keyers and I don't like it. I just don't get it or see the point. I would rather use single lever than fight with Mode B.

But, I've noticed that the Mode A on the ATS-3A and ATS-3B seems a little rough in some way, but I can't put my finger on it. I just seem to make more timing errors and get extra dits, stuff like that. I have a hard time using the iambic squeeze feature without getting an additional dit or dah, etc. I often end up sending without squeezing both levers, in effect, single lever sending, to avoid errors.

Is this me, or is there something slightly off in the way the keying is timed or programmed? I don't go very fast - 20 WPM average. I know there was/is a problem with Mode B.

I think my CMOS 4 keyer sends easier in Mode A, and even my TICK 4 and K10 keyers seem better - whatever it is must be subtle.

I like the idea of using an external keyer like the PALM - we also could probably wire a TICK or a K10 into the box, silly as that seems. Any experts out there?

Thanks

3665. RE: [AT_Sprint] Re: Ultimatic, Iambic Keying, et al.

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-16 21:09:37 UTC
From: Michael Harnage
Topic: 3627 Message: 3665

Thanks Ken. I worked with several high speed ops and another programmer to get the iambic modes working "properly" for my version of the firmware. (Note: I have not ported the improved iambic stuff to the ATS2/3/3A yet.)

On the topic of iambic keying: There is no single "standard". One can only try to find as much information as is available, then try to come up with an algorithm that satisfies the most people. It was only recently (within the last year) that there was an interest in improving the "feel" of the keying in the ATS rigs. With the help of some high speed ops that is what I did for my version. They seem to like it. Steve is more than welcome to incorporate what I did in his code as well.

On the topic of ultimatic: my impression is that not many folks use it. This thread is the first time I have heard of someone using it. My thinking is similiar to Jim Miller's. Why add it in the firmware, when you can do it mechanically with a single lever paddle or a dual paddle used as a single lever paddle with an iambic keyer? That said, if you are interested in ultimatic keying please let me know, either on list or via private email and if there is enough interest, I will see about adding it to my version of the firmware.

Couple of things I try to keep in mind when deciding what to add to my firmware:

#1: Is it something that I want? (Not an absolute, but afterall, this is how my interest in the firmware started.)

#2: Does it add too much? (This is a minimalist rig. Too many features will make it too complicated and then not attractive to its target audience.)

Back when the MPU was limited to 4K bytes adding ultimatic would not even be considered. But now with 8K bytes, it is in the possible catagory.

Caveat: I speak only for myself and reserve the right to put my wife, kids, and job first. In other words, any changes might take a while. :)

Wow, great to see this thread finally light up. I started it several days ago and was afraid it was doomed to total disregard.

I recognize that I'm something of a relic - a high speed Ultimatic op. After years of blissful ultimatic operation, when iambic keying and double-action paddles came along I didn't feel compelled to switch over since I was fat, dumb, happy and pretty proficient with my old stuff. As I got back into contesting actively about five years ago and started guest op'ing at modern stations I found I was distinctly in the minority with my non-iambic ways, and in fact was downright clumsy trying to use their dual action paddles and iambic keyers. Clumsy is probably too kind. I was (and am) terrible at it.

Now to my new ATS3B and Palm mini. I bought the Palm so I could travel light - why else have a radio in an Altoids can? The Palm's a super paddle, but it's dual action, and when hooked up to an iambic keyer it's Lidville for me. BTW, as has been pointed out in a previous message, I'm good to go with a single-action paddle and an iambic keyer. It's basically ultimatic (the keyer can't see both a dit and dah key closure simultaneously). To use the ATS3B that way, however, I can't carry my streamlined little Palm paddle. There's the dilema. The other alternative suggested was to use an outboard keyer that can run ultimatic. Same problem - more junk to haul - not the reason you play in the Altoids League.

If you find it possible to mod the code to add ultimatic it would be spectacular. I know I'm not the last living ultimatic user, but admit I may be part of a dying breed - then aren't we all?

Thanks for considering it Mike!

Gary;
I read that using a single paddle in the Iambic Mode works very
similar to the Ultimatic mode.
I don't know that for fact, but I have used a single paddle key, made
from PC Board material as a miniature key for my ATS-3B and it does
work fine.
Even my Scorpions kit dual paddle key I use as a sideswiper, never
'squeezing', only 'slapping'. It never seemed a big deal to use
iambic for me!

You can't be part of a dying breed if I, a potential new CW op, am interested in gaining CW skills with ultimatic keying. I don't have a radio, a key, or anything. In fact, I've been out of the hobby for around a decade, and it's the ATS-3B that's sparked my interest again. I learned CW many years ago to get my license (and now forgotten it), but the main reason I'm interested in the ATS-3B is for its digital capability. Nonetheless, I plan on using CW also so I can get the most out of it when I'm without a computer.

About the ATS-3, AE5X says "This is one of the most impressive radios I've owned or heard about in my almost 27 years of being in the hobby". That's a pretty powerful statement - enough to catch the attention of any gadget lover.

http://www.ae5x.com/ats3.html

I used to be pretty good at handling SMT / SMD surface mount soldering, but things have changed, and I no longer have any equipment. Once I've saved a little money, I'll probably try to buy an assembled and tested radio, with built in key if possible, so I can get into it without the expense of the solder station. I'm on a VERY tight budget.

3671. Run For the Bacon - Sunday night!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-19 00:59:54 UTC
From: Larry Makoski W2LJ
Topic: 3671 Message: 3671

Hello everyone!

Holy cow! Is it the third Sunday in October already? Where's the time going to?

The Flying Pig's monthly "Run For the Bacon" QRP CW contest is this Sunday night! The last one before Halloween and the last one before Election Day and the last one for this year in Daylight Savings Time!

This friendly, low pressure, 2 hour sprint runs from 9:00 to 11:00 PM Eastern DST.

For all the details, please visit http://www.fpqrp.com/fpqrprun.php

The Flying Pigs QRP ARCI is now maintaining an archive of previous "pig-runs" for your viewing pleasure.

See you in the troughs!

Hello all,

I was going to continue building the ATS-3b after a few months on the shelf. The board had oxidized at some places and that has to be taken care of before I can start soldering. My question is, what is the easiest way to remove the oxide?

Thanks,

Alex

3673. Building ATS-3b

3675. Run for the Bacon, 10/19/2008, 6:00 pm

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-20 00:41:53 UTC
From: AT_Sprint@yahoogroups.com
Topic: 3675 Message: 3675

Reminder from: AT_Sprint Yahoo! Group
http://groups.yahoo.com/group/AT_Sprint/cal

Run for the Bacon
Sunday October 19, 2008
6:00 pm - 8:00 pm
(This event repeats every month on the third Sunday.)
Location: Your shack or anywhere

Notes:
This Sunday evening, the Flying Pigs Amateur Radio Club International will be holding its monthly Run For The Bacon. This is a friendly, two hour QRP CW Sprint, which is open to ALL radio amateurs, will last from 9:00 - 11:00PM EDT (0200-0400 UTC Monday).

You may work stations once per band on 160, 80, 40, 20, 15 or 10 Meters. Suggested starting frequencies are 1.812, 3.562, 7.044, 14.062, 21.062, and 28.062 MHz.

The exchange is RST, S/P/C (State, Province, Country) and Flying Pigs membership number. If you're not a member of the Flying Pigs, and would like to be; then please cli

3676. Re: Ultimatic, Iambic Keying, et al.

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-20 20:44:17 UTC
From: k5jfp
Topic: 3627 Message: 3676

I think my biggest problem with iambic is that I was already deeply entrenched in ultimatic technique, and trying to change was something akin for me to learning how to write left-handed after spending most of my life writing right-handed. My advice to you, since the manufacturers of most modern day radios assume all us ultimatic relics have passed on to the big paddle in the sky, would be to "go with the flow". Since you don't have anything to un-learn, just get yourself one of any number of dual-action paddles and start from day one to send iambic. You won't have missed anything, and won't spend time like I do on bended knee begging for workarounds to a problem you don't have to have.

Glad to have a "new" CW op coming into the fold. All you have to do is tune across the bands to know that CW is still very much alive and well. Watch the scope on a modern radio on a major contest weekend and you'll be hard pressed to find a hole anywhere!

I would also suggest (though my build job was FAR from perfect) that it's possible to do a respectable job of building an ATS3B without an expensive solder station. You DO need good eyes, good lighting, a steady hand, fine tweezers, solder wick (copper braid) and some magnification assistance to build the radio. If you don't have a soldering iron at all, for under $80 you can buy an ESD-grounded, fine-tipped variable temperature iron (like a Hakko 936) that will put you in the soldering big leagues, but you can get by with a lot less.

73,

Gary W5ZL

I think.. just maybe... with all the input about the different keying... I just may have found out
why... after so many years... why exactly the little homebrew - 7 IC - battery powered - relay output keyer in a bud box with sidetone and built in paddles... all for the new key enthusiast...
me ... didn't work right... try as hard as I could... and did... ruined ... oh I don't really know.. but at least a hundred or even more.. sets of ears, trying to make a little sense of what I was sending, just couldn't do it. Then, after a whole bunch of months... and finally.. finally... I found at a hamfest somewhere... a cute litte keyer.... brandy new, well sorta... then... was a new style keyer.. and the fellow didn't want it... but I suspect... just maybe... he may have been one to have heard me.. on the air... limping along. Well anyway.. here he is, with this " new fangled thing.. can't make it work, would you give it a try?" situation.. I couldn't pass it up... price was right... and low ... it happened. ... Squeeze paddles.... so... suddenly... there came sweet, smooth, and pretty nice sounding, cw... from my own finners.. WOW!
Yep, sucked me in... since... I have tried most all.. keyers, keys... and even a TO keyer...
but you know.. the squeeze key works the best.... for me.
You don't suppose it has something to do with me being left handed... key with the right while typing or writing with the left? hmmmm.... and another question is born. --...

3678. Pre-Drilled Enclosure

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-21 00:25:00 UTC
From: nwgarner
Topic: 3678 Message: 3678

Hello Everyone,
I've eaten way too many Altoids and have been through four iterations of drilling to get the holes right but it doesn't come out as I'd like it. I've since made an enclosure out of the rosewood you can get at Michael's but it's not very rigid. Is anyone selling an ATS-3B compatible enclosure, pre-drilled with a professional look? I'd like to be able to put a BNC connector in it as well.

Nick

Nick,

I can't help on a pre-drilled enclosure but I've spent the last two weeks drilling lots of holes in Altoids tins to hold several antenna tuner prototypes. I've been pleased with the results of the drilling. Unfortunately, the tuner itself has a ways to go! <g>

I start by marking the hole location with a carbide tipped punch to keep the drill from wandering. I back the area to be punched with a piece of wood to keep bending to a minimum. I use the smallest drill and increase the diameter in steps until it matches the 1/8" tip on a 1/2" diameter Uni-Bit. Then I use a Unit-Bit to finish the hole.

It took me several attempts to realize that unless the Uni-Bit is running at top speed it grabs the thin metal of the tin with predictable results. Done right the holes perfectly round and the Uni-Bit does not wander.

I also have what machinists call an edge breaker. This rotary hand tool cleans-up the outside edge of the hole. For clearance reasons it won't clean-up holes drilled in the sides of the tin from the inside. For the inside sides I use a larger drill bit or a handloader's deburring tool.

Hope this is helpful until you find a pre-drilled enclosure.

Dave, NF0R

I thought I had seen something about a CNC machined aluminum alternative to the trusty Altoids tin, and after a bit of a search found it. You can eat a lot of Altoids for the price (twenty-four bucks), but it looks like it might be pretty substantial:

http://www.americanmorse.com/aa1.htm

Legal Disclaimers: I've never seen one of these. I don't have a pecuniary interest of any kind. Your mileage may vary. Make a legal U-turn.

From: qwasty
Topic: 3627 Message: 3681

If I understand you correctly, you don't think Ultimatic mode is good enough to be worth being different? By the way, I type with a Dvorak Typematrix keyboard, and I'm glad I ignored everyone that warned me away from being different. I won't touch a QWERTY anymore, no matter how many people's slimy hands have stickied it up. I'm surprised people think of that as being a point in favor of QWERTY, haha.

I take my Typematrix with me so I can type the way I want. I suppose I could do the same with a keyer, if it offers me something in return. A Typematrix Dvorak is definitely worth the hassle, since it doesn't hurt to type with it, but what about Ultimatic CW mode? Is it not that much better than Iambic in your opinion? It may be moot if I end up just doing my CW via keyboard. I'm not sure how much stamina I'll have sending by hand, but I'd like to try.

I used to use a fancy SMD SMT solder rework station, but that was so long ago, I can't even remember the name. Right now, I'm so poor I can't even afford a $10 second hand radioshack iron. I have a friend that has access to the local university labs though, and I bet I could get some favors there. We'll see.

Topic: 3678 Message: 3682

I used to be a machinist. I used to make missiles and other flight hardware, but now I look at that stuff and drool, even though it's only a box. That's actually not a bad price. If it were a government job that box would cost $ 2400 instead of $24. I'd probably buy one just to save the tooling and setup costs, but I'd want to stick a silicone gasket on it to make it waterproof. Since it's aluminum, you can use a hammer and a push pin to make a starter hole for a drill. If your drill is small enough, like 1/8th inch, you could drill it out by hand with a little common drill pretty easily. You could use a dremel sanding tip to make it big enough for your connectors. No fancy tools necessary! It'd look great if the manufacturer would get them anodized in various colors, and it would keep it from scratching. 6061 aluminum is soft, and dust on a desktop will have no trouble scraping it up.

--- In AT_Sprint@yahoogroups.com, Dale Putnam <daleputnam@...> wrote:

Dale,

Congratulations on getting a new keyer. They certainly aren't all the same.

Just wanted to say that I also am a left-handed writer but a right-handed CW sender. I use most hand tools in the right hand first, so maybe I'm really a little more right handed - but I learned to draw early, so it went to the left hand. When I was about 11 I started to learn CW, and I had a fight with myself about which hand to use with the straight key. I decided on the right hand for the key so I could write with the left hand and not have to switch hands, etc.

I can't type worth a hoot and use four fingers.

They call us "mixed ambilaterals", I think. It's nice to have two hands and two brains connected together.

To the folks building their ATS-3B kits, I suggest searching this site for all the material we posted last year about this time. There's plenty of good material on SMT technique, the Cash Olson hot air soldering method, other methods and tools, etc. Use the SEARCH tool to find this material. Also please look at the pictures and files we have posted here...lots of ideas and answers.

I'd recommend opening a small hole with a drill (use wood backing) then with a grinding stone in a dremel, it takes only seconds to fit to size with no danger of tearing the metal.

I put my ATS-3A in an American Morse box. See pictures in the photo section under "N6GA's scope photos." I used a Unibit, it worked like a charm. A tad sturdier than the Altoids,

Is there an advantage in using Iambic keying? Within a year, or so, a post on QRP-L referenced an ergonomic study comparing the two methods of keying. As I recall, the conclusion was that Iambic keying was more efficient on some letters of the alphabet, but it was sufficiently less efficient on the remaining letters to lose its advantage. Apparently, the letters on which Iambic keying is more efficient are less commonly used.

I learned to send on a tube HB keyer that my brother (Craig WA1BXP [SK]) and I built in the early sixties from the Handbook, I think. We made a paddle from some curtain rod brackets and a hacksaw blade broken into halves. I think that old key is the reason I today have no problem sending Ultimatic with an Iambic paddle, all though I prefer the former.

Date: 2008-10-23 07:58:45 UTC
From: qwasty
Topic: 3689 Message: 3689

Here's an interesting tiny little key. It's about the size of a quarter. It is probably a better match for the ATS-3B than the Palm Radio Mini Paddle. It's a fraction of the price too, at only $20. I could save for a fine Begali key for fixed use if I got one of those instead of the Palm paddles, for portable use.

I may have the distinction of getting the last Micro key from Dennis Foster. Any of you that follow the adventures of N0TU & Rooster/Peanut may have seen the Micro that Steve sometimes uses. Steve calls his a TE-NE-KE, which is another manufacturer of the same design and more info can be found here: http://www.qsl.net/noarc/newneke.htm

I contacted Dennis last Spring and he dug around and found one and sent it to me. I understand that he suffered a fire that wiped out his materials, tools and jigs. Basically it put him out of business. Too bad, as this is a very small, light and remarkable paddle. I did have to repair the cord attachment a couple of times, as he used very flexible light wire. I have recently put on a new cord that's pretty stiff by comparison, but its a shielded pair that looks like zip cord, from an old computer speaker, and I think it will stand up well.

From: qwasty
Topic: 3692 Message: 3692

OK, if you want to go portable and light, with quick and easy setup and take down, is it best done with a simple little wire antenna and a "big" tuner, or with a big resonant antenna with feedline and no tuner?

Actually I use the best of both worlds. Simple, portable and
lightweight YET FULL SIZED antenna with quick and easy setup and
takedown. It is resonant and requires a *simple and lightweight*,
(resonant) feedline that is EXCEPTIONALLY efficient. No tuner is
required either. Nor is a balun needed (ever).

It all fits in my pocket too.

I don't know if you consider this a "big" tuner, but it makes a tidy
little package. This tuner also has the Tayloe bridge which the ATS
rigs like to look at.

For me its a 50 foot end fed zepp and a small tuner. Its not too much wire, only one end neds to be erected, and a small tuner, BLT, T-Match, LDG, T1, etc. each work fb and are easy to carry along.

If by portable you mean backpacking, then a plain wire and a vy small tuner is hard to beat, ie. 50 -55 foot wire and an ALT.

Many folks like the ease of a lightweight resonant dipole for ease of use also. But you have 2 ends to hoist and need one for each band. Everything's a tradeoff, eh?

I love this radio stuff !

Here is the response I got from querying the president of the NOARC
regarding their TE NE KE. Note that he says the Micro and the TE NE KE
are the same design, the most notable difference being that the TE NE KE
has a base attached, but which could probably be easily removed. I have
mounted my Micro in a slotted wine cork like I noted that N0TU had
done. This give a bit more to grip and works well. You can see this on
Steve's site: http://www.angelfire.com/planet/goatman/ATS3a.html

TGIF!

I had forgotten about my Micro paddle until this thread got underway. Some drawer searching ensured. I just plugged it in my K2 and still works as well as I remember.

Dennis did a super job with his various designs. My sense is rolling your own would not be too difficult. The critical component seems to be finger stock which serves as both contacts and fingerpieces. They need to be bent precisely.

I used the Micro portable for several years as a two-handed paddle. I like the idea posted earlier about using a split cork as a holder to make it easier to manipulate - especially in colder weather. I must try that.

I currently use a St. Louis Paddle (QRPp Winter 2000) for portable including with an ATS3B. It is a single lever design based on a 1/4" plug and can be used on a cable assembly or plugged directly into a socket in the panel of my homebrew 20CW station. Nothing remarkable but it is an easily homebrewed, lightweight and low-cost option.

This little paddle's exposed lever is somewhat fragile and spacing changes with big temperature swings - i.e. FYBO. Adjustment entails bending contact arms which is an in-exact science and always easier at home than trailside.

I am planning on adding a CW Touch Keyer to the ATS3B. I have already prototyped a SLP for fixed fingerpiece keying. This will eliminate adjustments and for all practical purposes the paddle should be bulletproof.

>

There are no easy answers here - but you can try all kinds of combinations if you get outdoors with your radio.

I like the dipole, ladder line, and BLT for ease of use, efficiency, and multiband operation. I have backpacked with this - I used an 85 foot wire. Not the lightest combo, but it's good. Use more wire if you're planning on 80M at night - likely this fall and winter - or settle for a shorter dipole if you're on only during the day.

On a recent backpack trip I used an inverted L and my homemade ALT. I operated on 40, 30, and 20. Try 55 feet, or maybe about 80 feet. for the antenna, and use a short counterpoise - like 16 feet or less. For low power you don't want a high-current standing wave near ground - you want it as high as possible - so forget the common advoce to use a quarter wave counterpoise. If you don't believe me, model it with EZNEC and see what I saw - the signal get stronger as the counterpoise gets shorter, within reasonable limits. No feedline is required for the INV L and counterpoise. The wire can be diagonal - one support - and will work fine.

Experiment, try stuff, take some extra wires with clips so you can change lengths to get a better match. ALWAYS run the ATS rigs with a match indicator (Dan Tayloe LED bridge like on the BLT), always run with a really good match, and always use a tuner of some kind unless you want to work on your rig. If you run 12V and 5W out the tuner is required. The results are really fun, like you really can call CQ and get contacts, you can have long ragchews with QRO guys, etc. It's a kick.

I'll be operating my ATS-3B this weekend, Saturday night, probably at 7.03-7.04, from a campsite in the mountains at 9000 feet. I'm thinking dipole or inverted V.

The inverted V only needs one support. If long, light strings are used on the ends, the droop is minimal, even if they tie near ground level. There is no real need to erect the antenna in a line - the models show OK performance even at at right angle.

Two 75 foot wires in a horizontal Vee, with an angle of 45-55 degrees, make a nice 40M and 30M antenna. Radiation is at a right angle to the line bisecting the Vee. This is a variation of the W8JK. You can scale this for higher bands.

Be flexible. The trees or other supports will tell you what to put up. I recommend doing some modelling so you can know what to expect when you put up wires and have to go with whatever is available.

Higher is usually better, unless you want to work NVIS (high angle skip). 30 feet gets lots of Q's. On mountains and hillsides less will work amazingly well. More is awesome.

If you want some gain, try an extended double zepp fed with ladder line and a BLT. It has narrow lobes but works well. AN EDZ for 20M will work as a dipole for 30M and 40M, providing you have a decent balanced tuner.

My favorite QRP antenna is the horizontal loop, cut for a full wave on 40M - about 145 feet around the loop. Feed it with ladder line or 300 ohm twinlead. Works well on 40 and 20, even other bands. It requires at least 3 supports, so it's no picnic, but there's no need to make it equilateral or even symmetric. Modelling shows this antenna to be very tolerant of putting it where it will go up. This one will delight you every time. It has the advantage that it works well with trees - it doesn't need to run through the branches the way a center-supported dipole usually does.

Vertical loops work well too, and some of them work well with a single high tree.

Fun activities!

Putting up antennas gets easier the more of them you do. Start simple and then let your fantasies take you places.

From: qwasty
Topic: 3627 Message: 3702

I'm still somewhat new to this. I can see how a single lever set between two different switch contacts (SPDT?) could function like ultimatic mode. But, I've never even seen a single lever iambic key before, so what's the practical difference compared to double lever pair of paddles? It seems to me that the wide width of spacing is the only advantage the pair paddles have over a single lever, and the single lever could easily be wide enough by design. So, all the other advantages go to the single lever design: Ultimatic mode plus it's simpler, more reliable, easier to homebrew, and easier to adjust. Am I missing anything? Pair paddle iambic doesn't seem to offer much, if anything, over a single lever ultimatic design, other than the fact that I've never seen a commercially produced version of the ultimatic single lever key.

qwasty...don't confuse the keyer with the paddle.

iambic keyer - when both switches are pressed outputs alternating dits and dahs.

ultimatic keyer - when both switches are pressed outputs a stream of either dits or dahs depending on which was the last one pressed.

with the single lever paddle both iambic and ultimatic keyer will act the same since the switches cannot be active simultaneously.

the dual lever paddle is necessary to allow simultaneous switch closures when using iambic or ultimatic modes. an iambic key must allow both switches to be closed, therefore there is no such thing as a single lever iambic key.

personally I'd stick with the iambic simply because it is more common...otherwise you risk being a lid when using someone else's setup. ;-)

one thing I would like to see is a "bug" mode. I have yet to see a decent backpacking bug, so I had to learn both iambic and bug, which means I'm not really good at either (that's my story and I'm sticking to it!).

I have a handful of batteries that need to find new homes, before wasting away here.
Professional grade alki batteries,
both sizes - could be yours, AA - 8 for 10 or AAA - 16 for 10, or package the two together and get 24 batteries, just in time
for the Christmas rush, and I'll pick up the shipping.
I also have 2600 mah NiMH rechargable AA they should sell for well over $2, if you want to build up a 12v pack, you'll need 10,
and you can have enough for the job, for only $20, and I'll pick up the postage.
Email me off list please, I will take paypal to make it real easy.

3705. How to get an ATS-3B?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-26 23:12:56 UTC
From: qwasty
Topic: 3705 Message: 3705

I've been reading here for a while, and thinking about things, and I've decided to get back into the ham radio hobby after many years off the air because of this radio. How do I get one?

I prefer one that's already built and adjusted because I don't have any equipment of any kind whatsoever, so I'm totally starting from scratch, and I can't afford to do much other than get the radio and some batteries, and maybe make a crappy wire antenna to receive with. I'll have to wait on everything else for now.

If I can't get one that's already built, I suppose I can get some help from friends who may let me use their stuff to get it working.

Is there a new version coming out? Usually long delays in new production means there's something going on behind the scenes. I'd like to get the most recent version if I can. I passed on some cheap MFJ cubs because I want to do digital modes, and this radio is the most capable of inexpensive radios.

What do you all think?

3706. Using Flux With Solder Paste

Yahoo group: AT_Sprint (2002 — 2008)

From: Jim Fraser
Topic: 3706 Message: 3706

I am soon to start on my second 3B this time using the solder paste/hot air method. In doing some practice with the Cash Olsen paste I just received, I find that the paste does not tend to stick to the pads and parts too well. As a result the embossing tool blew a few parts of my test board. Would it help to put some flux on the pads before applying the paste? I think I saw this done on some hot air soldering videos on YouTube.

The creator of the rig, Steve Weber KD1JV, mentions on his web site that he may have another run of the ATS-3B kits around Christmas. Keep an eye on his web site.

http://kd1jv.qrpradio.com/

Better yet, keep an eye out here on the group as kit offerings are usually announced here first!

Perhaps you could email him and let him know you are interested in getting a kit, this may help him decide to go ahead with another run. I picked up my second ATS-3B in the last run and will be starting to assemble it soon. Going to try the hot air soldering method this time.

Jim,

If you got your 3B from the last batch, did you get your solder paste
then as well? It seems to me that yours might have dried out? I had
no trouble at all with parts staying in place and have heard of people
dropping a board with parts stuck on with the paste and all was well.
I'm not aware of using flux with solder paste, but then there are a lot
of things that I'm not aware of.

--- In AT_Sprint@yahoogroups.com, steve d <kc8qvo@...> wrote:

Steve,

There were at least two runs of the ATS-3B. There were at least two runs of the ATS-3A also. I don't know the earlier history, but there were several models over several years, and possibly multiple runs of some.

There were changes in code between runs as well, and many operators may be running code with a few bugs.

Updated code from Steve Weber is available here, and Mike W1MT offers his alternate code as well (I still want to try it).

Does anyone have a history document posted here on this site?

With an ATS rig you can get that backpack load down to a few pounds - or even less, if you make choices and are creative.

I'm already at the point where the weight of the rig, band modules, paddles, headphones, battery, tuner, and cables is roughly the same as the antenna, balanced feedline, support lines, and fishing rod used to put up antenna.

If you settle for just one or two bands, make a really small tuner, use small wire, and eliminate the feedline, you can cut the weight and bulk considerably - but you lose a lot of flexibility and maybe several db of precious signal.

There's room for lots of work and development here. We're nowhere close to having ideal portable multiband systems. The tradeoffs are cruel, and there aren't many sunspots to help. The ATS rigs are so small and efficient that they've turned the portable game upside down - now all the weight problems are in the rest of the system - the radio is almost nothing!

There also are tradeoffs in the TIME required to erect efficient antennas vs. simpler and less effective antennas. Many times I've taken an hour or two to erect a dipole with three supports in the trees, including pondering the problems...and another voice in my head says "Just put up one line and make it a vertical or a sloper, and save yourself some time and get on the air quickly! Many times I've used a nice balanced dipole, only to make a contact with a station located well outside the directional signal pattern, and the thought has occured that a vertical might actually work better than a

dipole 10 db outside the pattern max!

Of course you can put up a couple of dipoles at right angles, and
that's a super system, but you have to carry twice the wire and
feedline, plus burn some more precious time getting it all up where
you want it....a perfectionist's nightmare.

Beware that QRP portable is often frustrating, it's full of surprises
and problems, and things rarely work out just the way you plan.
Either there are not enough trees, or there are way too many.
Sometimes the weight and line go right over the tree at just the
right spot, and then it gets stuck in the branches and won't drop.

It's really fun if you don't mind the hassles - it's really a game
where you make some of the rules and then adjust to everything else.

You can do a lot with 3 or 4 pounds!

All,

I noticed that my paste became drier and less sticky during the long session last Halloween night when I placed and soldered my parts for my "B".

We have very low humidity here. I think that moisture or perhaps some solvent like alcohol evaporates from the paste.

In the commercial environment boards loaded with parts normally would not sit around for long before being run through the oven to reflow the solder. The time that the paste is exposed to air is usually not several hours or more.

On commercial production lines, the paste is printed on the boards with screens, and it must stay where it belongs and also hold the parts that are placed by machines. Consistent behavior of the paste is critical to the process.

Others have suggested doing the board in sections, and this might be good.

Hopefully someone who knows more about the paste can tell us if whatever evaporates from the paste can be "put back" - like can the paste be made sticky by adding a little water or alcohol?

Of course, others have suggested keeping the paste in the refrigerator for storage - just be sure to let it warm up before using it.

Maybe we should ask Cash Olson...

Thanks for the info, Carey.

You outlined some of my exact problems over my 3 day trip. I took my 857, NorCal doublet, and 971 tuner by Mighty Fine Junk (minus the front panel and top cover to shave a bit of weight). The biggest issue I ran in to was finding a tree in the right place when putting up my antenna. The second night I decided to plan where I put the tent around where the trees were. This still didn't work to well. Since I was with a group where I was the only ham it was a bit more frustrating in not having the time to really sit at the rig and try for many QSO's. The temperature also played a big role in that - I was in the tent to sleep and try to stay warm HI. At temps in the mid 20's Saturday night and not being equipped for it, the radio was about the last thing I wanted to mess with!

All in all I had 15lbs of radio gear - rig, tuner, antenna, battery. The weight never really came across as a problem. It slowed me down going up hills, but that was about it. The rest of my soreness and rashes would have happened no matter if I had 50lbs or 35lbs.

I need to get some new backpacking gear regardless of the radio - tent and sleeping bag mainly, plus a few clothing items. That should shave some lbs there and make me more comfortable.

Heres the rest of the story:

http://www.kc8qvo.com/2008/10/backpacking-in-dolly-sods-wilderness.html

Steve,

There were at least two runs of the ATS-3B. There were at least two
runs of the ATS-3A also. I don't know the earlier history, but there
were several models over several years, and possibly multiple runs of
some.

With an ATS rig you can get that backpack load down to a few pounds -
or even less, if you make choices and are creative.

Beware that QRP portable is often frustrating, it's full of surprises
and problems, and things rarely work out just the way you plan.
Either there are not enough trees, or there are way too many.

Sometimes the weight and line go right over the tree at just the right spot, and then it gets stuck in the branches and won't drop.

It's really fun if you don't mind the hassles - it's really a game where you make some of the rules and then adjust to everything else.

You can do a lot with 3 or 4 pounds!

Thanks for the info and notes, Scott. Yeah, I do have a thermarest trail lite reg pad. I bought it last year and haven't gone camping anywhere without it since - even in the heat of the summer. Thats the green thing rolled up on the top of the pack in several pictures on the blog.

As for lots of juice with the 857 - yep. I took a 12ah SLA. I was anticipating working JOTA but as it turned out I didn't. I just recieved with the rig mostly. I did try for a few QSO's but every time I got on there (40m cw) someone was either on my frequency already or took it after I claimed it. Oh well. Better luck next time I guess.

Steve:

If you like 40/30/20 metres, the Portable Field Radio (PFR-3) is essentially a 3 band version of the ATS3b, complete with a digital display, a antenna coupler, and a nice enclosure, for around $200. It is available from http;//www.qrpkits.com. It uses discrete parts, except for the CPU and some other surface mount parts, but these are installed at qrpkits. It has band switching vs plug in band modules for the ATS3 series, otherwise it is "essentially" a close variant to the ATS-3b.

If you don't mind being limited to 2 bands, KD1JV is promising a 2 band rig, with choice of any two bands, to be released sometime in the near future. I believe that qrpkits will be offering that kit also.

Kurt:

KD1JV has said that he hopes to have another run of the ATS-3b kits available for Christmas. That was early this spring, before he went on an extended hike along the Appalachian trail.

But, several folks have had glowing reports about the PFR-3, because of the ruggedness, visibility (bright yellow), the fact that it has a digital frequency readout, is completely self contained including an antenna coupler, etc. I hope I have some "stuff" sold by the next time the 3b kits are available because of it's lightness, and the fact that I like 80 metres, which isn't available on the PFR-3.

Well, my solder paste is definitely not as creamy as what I see in all the videos on the web, even after letting it warm to room temperature before using. Last year I had also ordered some paste from Cash for a SoftRock project and it was also on the dry side. Maybe it dries out too much in the shipping from NM to CA?

On the tube from last year I added a few small drops of water which seemed to soften it up a bit, may need a bit more. Its worth a shot.

If all else fails, there ia a local source that sells solder paste I may try. It is more expensive at $15 for 15 grams, but at least I can check it out before buying it.

Woo Hoo!

After a few emails back and forth with Michael Harnage about iambic parameters, my ATS3B now has a totally new iambic feel that I am extremely happy with.

I apparently had learned code on a keyer that emulated the "Accukeyer". As it turns out, the Accukeyer is an exaggeration of the iambic B-mode.

Some key differences (no pun intended) using the letter "C" as an example:

-- Mode A iambic generation of the letter "C"
squeeze both paddles (dah before dit) and let go of both after hearing the last dit.

-- Mode B iambic generation of the letter "C"
squeeze both paddles (dah before dit) and let go of both after hearing a certain percentage of the second dah.
note.. the ATS3B mode-B is 50% (other rigs may be less)

-- Accukeyer iambic generation of the letter "C"
squeeze both paddles (dah before dit) and let go of both after hearing *any* percentage of the second dah.

There are two timing loops (labeled dita and dota) that Mike showed me in the ATS3B firmware code that can be remarked-out to convert the current mode-B to Accukeyer. After remarking-out those two timing loops, I found that keying the ATS3B was a wonderful experience. Your mileage may vary...

Thanks Mike!

It's kind of a shame that the best solution to getting an ATS-3B is to get a different radio. I understand this radio is a labor of love, but I'd like to mention that many good businesses fail because they can't keep up with orders. If supply never catches up with demand, eventually demand shifts elsewhere. I think this radio could do really well from a business point of view because it can do multiband digital in a tiny little package. If it were available assembled, tested, and packaged in a neat little unit, I'd buy it, and I'm sure a few thousand other people would too. Make a small 10 to 50 watt amplifier available, and a few thousand more will buy it. Add a few more features and it will be competive with radios like the Icom IC-703 Plus, except at half the price or less, with better performance, and focused on the almost totally unserved CW/digital niche market. Off the top of my head I can't think of a multiband radio focused on digital.

If any of the deciders are reading (KD1JV), I think this radio might be nearly ready for prime time if only it were available. Maybe you've already thought of that too. What do you think?

--- In AT_Sprint@yahoogroups.com, "qwasty" <qwasty@...> wrote:

Perhaps a different viewpoint here....

The PFR-3 is really the "people's version" of the ATS-3 radios. It is more rugged, is easier to build, and is much more complete than the ATS-3 radios.

The ATS radios are really designed for a small cult of operators who want the lightest possible unit, are willing to accept a delicate device, are able to complete the challenging SMT assembly, and who have the patience to build and adjust the filter modules.

The radio is a direct result of Steve Weber's own backpacking experience and his dream to have a radio so small and light that he could actually take it on tough trips and make real contacts. I doubt that it was ever intended as a big money maker. We are fortunate that Steve has shared it with us!

I think that only a few people have actually used the ATS-3B for digital modes, but the digital features open up the incredible frontier of tiny HF radios communicating digitally over large distances from remote places. This is a cult within a cult here! This is only the beginning. In a few years it will be possible to take tiny HF radios into the woods, communicate reliably and error-free at some acceptable rate, with less than a watt of power.

There are some real commercial possibilities here.

I love my ATS-3 radios, and I've had incredible fun with them. I'll always be grateful to Steve for working so hard to make this whole thing happen.

Even so, the ATS rigs are terrible entry level radios. They're tiny, sophisticated, specialized tools, and they're intended for people who've grown up with larger, more forgiving radios.

Several other companies offer a selection of nice QRP radios, many in kit form, that are much more suitable for newer ops or those with a broader range of interests and goals.

What I'd like to see is an ATS derivative that could run CW on 10 meters, and perhaps other bands. Even a single-band 10-meter dedicated rig would be such a kick to use! In a few years we'll have solar conditions that will let us work other continents with a couple of watts and a 17-foot dipole, or a whip vertical, from almost anywhere.

I know Steve was close to getting the ATS-3B up to 10 meters, but doing that would have compromised efficiency and other details of the design that we like. Nevertheless, I do think that if the timing were right, once 10 meters is open again regularly, many of these hypothetical 10 meter rigs could be sold to a global market. 10 meters is full of miracles when it's open, and QRP portable on 10 would be an ultimate experience.

We can dream...

What if the ATS-3B were packed into the NUE-PSK modem, and they shared that big fancy display (by QRP standards)? That'd be a radio everybody could use whether they're into CW or not. It'd also be an impressive survival or backpacking radio.

What if I'm the one that gets hurt in my backpacking group and I'm not able to operate the radio? A PSK31 setup like that could be operated by anybody in an emergency situation with only a few minutes of instruction beforehand.

People who aren't functional in CW don't have many options in the QRP world, so they're almost totally unserved and excluded by the QRP ultra light portable cottage industry. Maybe the ATS series of radios can suck them in with it's digital capabilites.

Speaking of ultralights, I've always wanted to get into flying ultralight aircraft. Naturally, they can't carry very much, and a teeny radio would go great with them.

Just some thoughts.

While we're dreaming, what I'd REALLY like to see is an ATS derivative covering 10 and 6. (10 can be "miraculous," but they don't call 6 "the Magic Band" for nothing.) I would think that combo alone would be a sure winner.

Then after that we'd need a 2m, 1.25m, and 70cm version. Then, we'd need a microwave version 1.2ghz to 24ghz. Isn't there a ham band around 900mhz? That one we'll leave out so that people can still find something to improve on.

The "problem" with higher bands is that a higher clock speed is necessary for the frequency sympathizer (DDS). As I gather, the clock speed must be 2X or greater the desired output frequency, perhaps even more. For 6 metres that would mean at very minimum a 110 MHz clock speed.

Other suggestions have been for 160 metres, for inclusion of 3 or 4 digits in a digital readout, etc. Most of us folks, including me, are illiterate dolts when it comes to the fine points of transceiver design, so we keep begging for more!

It appears to me that Steve has done wonders within a limited budget to get the ATS-3b designed, debugged, and developed to this point.

But, dream on - maybe Steve or someone else will expand the ideas presented.

I wasn't at all suggesting an 80 (or 160) through 6 (or 2, or whatever) ATS-XX. Although I'll be the very last to denigrate Steve or his remarkable design accomplishments, such an assignment might tax even his abilities and budget.

My "dream" high-sunspot-number QRP rig covers only 10 and 6 (CW-only OK), but remains small, light and very portable (on an Altoids-tin scale). And I have to think I'm not the only one who feels that way. But, as Hank properly points out, such a rig would likely take a good chunk of fresh thinking by someone far more knowledgeable than me (us).

Good it doesn't cost anything to dream (yet).

72,

Mark -- WA9ETW

P.S. I also agree that, if you try to add everything but the "kitchen sink" to the ATS-3A/B, it won't be an ATS-3A/B anymore. Steve really hit the sweet spot with these purpose-designed/built rigs. They are what they are (iconic?), and fulfill their intended roles to a T. Don't mess with success!

What Steve has done is design the world's most practical and affordable trail radio and then shared all of his work. What else compares?

The first time I saw it on his web site, I was truly in disbelief.

There aint nothing bad about this radio!

It weighs what, 3 oz? (again, what else compares?)

It has a built-in keyer

It has a crystal lattice CW filter

It has open firmware source code ***WOW****

It will send almost three watts with only nine volts

It uses DDS

It uses commonly available parts

It has a built in battery meter

The list goes on..

I have learned a ton from this project.

Thanks Steve!

qwasty,

I don't recall seeing anywhere that the ATS-3B was a business venture, therefore I would prefer you not criticize as if it were so.

Putting out a kit such as this is quite a task...unless you are willing to give up your personal life. I know this from personal experience as I have participated in putting out such a kit. If you have any doubts about the extent of the effort involved, I would challenge you to try putting out your own kit.

I will suggest that if you are not patient enough to wait for the xmas (?) run, then maybe you aren't patient enough to put a challenging surface mount kit together. Spend the meantime making sure your kit building skills are honed, perhaps by building that PFR-3.

I apologize in advance if you think there was some "bite" in this email...that was not the intent. I was just trying to provide feedback regarding an email that would have royally pissed me off if it had been directed my way. ;-)

Steven is quite correct. Historically, Steve Weber would create a single run of kits for the general ham population. I personally suspect he just wanted to get a nice professionally made board for himself, so he would do a run of 50 to get a decent price on the boards, but I say this with tongue in cheek. It has only been since the advent of the ATS line of rigs that he has done multiple runs. Thankfully, he is opening up more and providing designs for clubs and actual business ventures such as QRP Kits to produce so that more can share in his designs.

3742. iambic algorithm

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-30 00:14:08 UTC
From: Steven Carr
Topic: 3718 Message: 3742

several years ago I coded up a project which had a iambic keyer included and tried investigating the iambic A vs B in regards to the actual algorithm used, only to find descriptions that confused me more than they helped. unfortunately I had to make some assumptions regarding iambic A and iambic B based merely on how I believe I would have designed the original circuits. what I came up with is that the main difference between mode B and mode A is whether the paddle inputs are latched or not.

since the original keyers were made with discrete gates and latches, one assumption that I made is that both iambic modes had to be easily implementable with the gates and latches in use at the time, therefore I refused to have arbitrary delays such as half a dah time.

iambic mode A is simple enough. press a key and an element (either a dit or a dah) is keyed out, followed by a space (1 dit-time). the decision as to which element is keyed out next (depending on which keys are pressed) is then determined based on the actual paddle inputs.

iambic mode A sounds great in theory and works ok, but what about scenarios like dit-insertion. hold down the dah key, tap the dit key, then release the dah key. the problem is if you tap the dit key too quickly then you get a M instead of a K because you released the dit key before the start of the next element (no dit key at this instant therefore no dit on the output). I made an assumption that iambic B was designed with input latching to allow some slop in the inputs so that the timing is less critical.

enter the latch. with iambic B, when it is time to key out the next element the decision is made based not on the actual paddle inputs but rather on latched paddle inputs. thus to key out a K hold the dah key and tap the dit key anytime before the dit is to be keyed...if you release "too soon" (w.r.t. mode A) you still get the dit (because of the input latch) that you would have missed with mode A. for my keyer (implemented in software) I reset the input latch for the element last keyed just prior to checking the input latches for the next element to be keyed. since the earliest keyers were based on gates rather than software I suspect for simplicity the input latch was reset while that element was being keyed out (thus reseting before the trailing space rather than after it, not a difference I would notice in operation).

the main thing that everyone not actually trying to implement a keyer seems to focus on is whether you get the trailing dit or dah. the reason for the trailing dit/dah is because that key's input has been latched.

I am curious about the mode A and mode B algorithms in the ATS-3B. also I would like to know if anyone is aware of a proper reference that describes, from an algorithm point of view, the iambic A and iambic B modes in enough detail that it could be used to confirm or deny my description above. since much of the above is based on "how I would do it", I'd like to know if it is spot on or way off. ;-) regardless it seemed to work well for me and I never got complaints regarding it.

also here is a link to a schematic of the Accu-keyer with gates and latches. note the latched paddle inputs. does anyone feel like exercising their digital circuits skills to determine what this thing actually does?

Mark,

I can think of three reasons we don't see many of these specialized low-VHF rigs:

1) Propagation on these bands depends on high solar activity, which varies. Anyone designing rigs for these bands would have to plan ahead so he could sell his kits while interest is high.

2) There are some pretty good arguments for double conversion. This avoids the high DDS clock, but it requires a more complex circuit with more mixers and another oscillator.

3) Much of the activity on these bands is SSB, not CW, and many customers probably would really rather have SSB. This again makes the radio more complex. If a linear amplifier is used, power consumption goes up. Now we need a larger battery....

We're already far away from the ATS design.

Nevertheless, today's technology makes a very small SSB rig for these bands possible.

Maybe someone is already designing this rig...maybe it will be one of MFJ's hot offerings in a couple of years...

Hank,

You're right about the DDS clock. Steve wrote a message about the problem many months ago. It's on this site way back somewhere.

However, our rigs might work on 160M if the firmware supported it - at least no one has said "NO" to this idea. The toroids on the filter module might have to be wound on something stronger than red #2 powdered iron to keep the number of turns reasonable. That's easy.

A fairly serious external antenna tuner would also be required. I have a BLT that covers 160M, and it's not rocket science - but you need something like that, especially if you want to run short antennas.

Never mind that the band is best in mid-winter, and most of us aren't doing QRP portable then. Putting up a dipole - or anything else full-size - for 160M in the woods in winter snow would take some determination.

However, I have operated on 80M in January snow at 9000 feet, with the ATS-3B, and it was fun. All I had was a 40M diple and a modified BLT, but I made QSO's and was getting out pretty well. I'll definitely do it again this winter.

Yeah, I wish it would run on 160 - just so I could say I did it - I've never operated portable on 160M yet. Maybe this year I'll drag out my FT-817...and a big battery...that radio eats electrons...

<jaevans@...> wrote:

John,

At the very least the ATS thing will go down as one of the most
incredible recent efforts in ham radio. Many people have found an
exciting corner of the hobby here.

Steve Weber has been a good listener - I know of several little
problems that he fixed in the "B" model - or that he told us how to
fix. He even reprogrammed some processors in at least two
instances! I can't imagine how he did all the jobs required to
release and support so many radios and other products.

The best kick is still coming - when we get high solar activity, we
can take these radios out for some amazing contacts on 20, 17, and 15
meters.

To extend firmware to support 160M is a piece of cake. Only issue may be detection of the newer band.

To support higher bands is another issue. The DDS in ATS-3b supports maximum clock of 70MHh. Recommended maximum generated output frequency is about 1/3 of the clock, which is 23MHz. Also steepness of the DDS filter will become an issue. To support higher bands reliably one either needs to use faster DDS or another approach (premixer like in K1 or analog VFO/VXO or PLL). Faster DDS will consume considerable higher current and produce considerable heat.

Another issue which is not that obvious is that there are higher requirements on the sensitivity and noise floor for higher bands. Look at the RX input circuit. The filter input is shunted by 50 ohm resistor. I believe the resistor has two puprposes. To attenuate antenna signal and to match filter impedance. The attenuation will became unwanted on higher bands.

Also dynamic range requirements are higher on higher bands. DDS spurs become an issue if there are strong signals next to weak ones, imagine contest situation with kW PAs and high gain antennas again. Strong signals will mix with DDS spurs and produce strong birdies. The difference in required dynamic range on low and high bands is caused exactly by high gain directional antennas.

3749. The ATS cult

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-10-30 22:41:14 UTC
From: J. Haynes
Topic: 3749 Message: 3749

Maybe it was Carey who said it, but 'cult' is very apt, given the difficulty I've had explaining theobsession to non-hams around me. Steve's design, along with JN1GLB's excellent frequency display mod, Vojtec's ongoing mods, and the contributions of so many have made it a really fun ride. I'm trying to goad Ken to reveal some of the commonsense mods that he's made to the W1MT firmware.
There's a lot of collective talent that goes into this culty rig.

3750. QBSA question

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-11-01 18:05:29 UTC
From: n8ewy
Topic: 3750 Message: 3750

My question is:

1. I see a place on the main board to connect a lead for the self contained power supply. It is, I assume for the positive (or hot) line. I assume this would go to the center pin of a DC connector. In the case of my 3-B, the 0.7mm power connector. Where does one bring a ground from, on the main board, to the outside connection of the 0.7mm power connector? Or don't you need to?

2. Are there any Mods that anyone can think of that have come up with since the QBSA came out? Any idea where to look them up? I have done some "googling" of the subject, but didn't come up with much.

Dohn:

That's how I did it. The hot line from the DC Input power jack goes to VIN and the ground lead to the pad G next to it. However, in my case I added a front panel switch in the hot line so that VIN is actually connected to one side of the switch.

There is only one mod I know of to increase the output voltage to 12v. You can find that in the Files section of this group. Good luck.

Dohn,

Please see several photos of my QBSA in the Photos section here on this site. These show how I did the wiring and connectors. Click on the "Large" photos and you probably can see every wire. You are free to do it any way you like.

In the Files section I posted instructions for how to increase the regulated power supply to 12 volts. This is optional and at your own risk. You'll need a higher input voltage, almost 15 volts, if you choose to regulate the output at 12.0 volts.

There also was an update to the code that was done for some of the later units - Steve was very helpful with this for some of us.

Good luck - the QBSA is a really neat accessory!

I had already seen this .pdf, but I certainly appreciate the effort.

Because of the lack of a real algorithm description I get the impression
that a lot of designers who try to implement iambic B are having to
guess at what it is supposed to be.

I'm pretty sure that iambic B didn't come around simply because of a
need for a trailing element, that's why I focused on the latched inputs
in my explanation of the iambic A vs B.

I can see the latched inputs on the AccuKeyer circuit, though I'm not
yet following the entire circuit yet. My main uncertainty is whether
the latches are reset before or after the trailing space in the
AccuKeyer circuit.

I did try reading the ATS-3B assy code, but I'm being hampered by my
unfamiliarity with that processor.

3756. ATS3B & QBSA for sale

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-11-05 00:07:40 UTC
From: n2uz
Topic: 2399 Message: 3756

I am selling my 3B and QBSA. I used RCA connectors on the Altoid tin for the antenna and frequency for the QBSA and I will supply 2 BNC/RCA adapters for them so you can just use BNC cables for both. Both units have Anderson power poles on the ends of their power cables. I have the filter boards in 2 other Altoids tins for storage. Comes with the CD's.
Price $165 for the 3B and $45 for the QBSA, or $200 for both. I would like to sell them as a set. I am selling so I can get the PFR3.
PayPal is preferred. Postage $7.00. CONUS only.
Jerry , N2UZ

3757. FET tool

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-11-05 02:55:42 UTC
From: Ken Lotts
Topic: 2399 Message: 3757

Does anyone use the TI MSP-FET430UIF?

I have just bought one (with the development board) and I have a few questions.

It flashes the ATS3B OK but it wont let the ATS3B run correctly while it is connected. Also I can not run the rig from the debugger. If I try the rig goes into overload with the "E" displayed.

The JTAG --> ATS cable was built as follows:

JTAG ATS
09 -- 01 GND
08 -- 02 TST
11 -- 03 RST
07 -- 04 TCK
05 -- 05 TMS
03 -- 06 TDI
01 -- 07 TDO

Cable length is close to 14 inches overall (from the extit of the FET to the entrance of the ATS3B

Another problem I am having is flashing MCUs that I put in the ZIF socketed development board. It fails every time with the error "No device found or device disconnected"

I have the MSP-FET430X110 that works from a parallel port and it does not have any of these problems.. I can run the debugger and watch the ATS variables.. I can flash a MCU in its ZIF..

3764. Butane Soldering Iron For SMT SMD work

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-11-06 22:37:10 UTC
From: qwasty
Topic: 3764 Message: 3764

I've been looking at some of the suggested soldering irons in this group. I'm wondering if a butane soldering iron can be suitable for SMT work? It's portable, just like the ATS-3B, and it can be used to start fires on a camping trip, or for impromptu solder fixups. The best part is that it can be used to blow heat, and maybe that would work well for solder paste.

Does anyone have any experience with using a butane iron for SMT SMD work? I did a google search for "smt butane iron" and I found one mention that Weller makes butane irons that work well as heat blowers, but it didn't mention WHICH butane iron specifically.

Like many people in this group, portability is key, and having a portable SMT workstation would just be ridiculously awesome. Almost as ridiculous as having a digital HF rig in an altoids tin, haha.

OK (FWIW) I figured out some of the problem.. First of all I was dyslexic. I bought the development board under the premis that it had a 28 pin ZIF socket for the MSP430F1232 but nope, it has a 28 pin ZIF socket for the MSP430F2132... a much smaller 28 pin mcu. for some reason I had not noticed how much smaller the chip was and the darn product number has the same numbers, just in a different order..... so once I compiled for the correct chip, I was able to get the test program to work on the development board. So all is well with the development board.

Now to figure out the reason the new FET disrupts the radio during normal operation just by having it connected.. probably a real easy answer as well..

Subject: [AT_Sprint] Butane Soldering Iron For SMT SMD work

I've been looking at some of the suggested soldering irons in this group. I'm wondering if a butane soldering iron can be suitable for SMT work? It's portable, just like the ATS-3B, and it can be used to start fires on a camping trip, or for impromptu solder fixups. The best part is that it can be used to blow heat, and maybe that would work well for solder paste.

Does anyone have any experience with using a butane iron for SMT SMD work? I did a google search for "smt butane iron" and I found one mention that Weller makes butane irons that work well as heat blowers, but it didn't mention WHICH butane iron specifically.

Believe it or not, I used a Radio Shack butane soldering iron to complete practically all of my ATS-3 (not -B) kit. It has a fairly small tip (much smaller than the only other iron I had at the time), and the heat is reasonably adjustable. It comes with a "blowtorch" attachment too, but I used the soldering tip.

Not sure I would recommend this to a newbie, but it can work. The butane iron now lives in my QRP toolkit that fits in a pencil box -- a twin to the box that holds my ATS-3, tuner, headphones, battery, etc. It's cool to think about making repairs in the wilderness!

My experience with blowing heat is with a Hobby Lobby embossing tool (12$). My soldering turned out well, and removing/reinstalling the MPU was a 40 second job, literally. Hold it with tweezers and it just lifts out. My only warning is overheating--I made a little focussing nozzle from a small kitchen funnel with a 1cm diameter opening. It worked well, but the heat was proportionally more intense. I actually saw the surface of the PCB blister up, much to my horror as I quickly flicked the tool away. It caused no damage to the radio, but scared me. Hot air soldering is really fast and easy, but overheating is one concern.

A bunch of us built our kits with the embossing tools - which means small hot air tools - from Hobby Lobby. This tool is amazing for what it is. It has the right amount of heat and just enough force to deliver it without blowing the parts off their pads.

The basic method can be found on Cash Olson's website:

http://www.zianet.com/erg/SMT_Soldering.html

You also can get some SMT solder paste there - a fair deal.

There are many messages here (stored on this site) about the hot air/solder paste method, plus many more about the one-joint-at-a-time methods. Both methods require patience and coordination, along with plenty of bright light and maybe more than the normal amount of caffeine....

I built an ATS-3A one joint at a time, and I did my "B" with the embossing tool and Cash Olson's paste. The paste method is a hobby version of commercial hot air reflow, and I believe you can do a real high quality job if you try.

The one additional recommendation I have applies to either SMT method:

Order a Norcal Dummy Load and build it first with the method you like. You'll get a useful, accurate QRP device, and you'll risk little. The confidence gained will help with building the radio.

Please use the SEARCH feature here if you want to read all the stuff we all wrote about a year ago.

Might work but is certainly a risky operation. I think the key point in the SMD soldering is the control of temperature and how fast you reach that temperature. With the butanol soldering iron you need a steady hand to keep the flame at just right distance. A small mistake and the components/board are damaged permanently.

OK, well first of all the rig had a virgin unprogrammed MCU in it that could not be programmed via the JTAG connector.
Pins 26 & 27 on the MCU were near zero volts compared to 3.5 volts on a working rig. Those pins were tied to both the DDS chip AND the JTAG connector.
The DDS did not have any shorted pins but I did not spend a huge amount of time trying to analyze why it was messing up the MCU.
My first interest was getting the MCU programmed so I removed the DDS (since it was pulling down the voltage on pins 26&27). After removing the DDS the MCU accepted the firmware via the JTAG.
I then put in a new DDS chip and the radio perked to life with no issues.

If you wick all the joints as clean as possible, the hot air portion of the job will be reduced to just a few seconds and thereby reduce possible component damage.
I use an Exacto knife to apply some wedging while I blow the hot air.

It sounds like a butane iron is not a good choice for a heat blower on a whole project, but maybe it's good enough for one or two components here and there? It would probably be easier to control if you were only doing one component, instead of trying to flow solder on the entire board all at once. I guess that could be generalized to say that no soldering iron can compete with a good heat blower for flowing solder on an entire board, but that they can be used for individual components. Does that sound about right?

This only applies to multi pin devices.. simple SMD parts like resistors and capacitors etc can USUALLY just be blown off with the air nozzle. The idea is not damaging the board so always keep an eye on the temperature and exposure time.
The term "Wedge" refers to the action of prying the chip away from the board.

Wedge the blade so that it applies a force that will pop the device away from the circuit board once the solder is no longer firmly holding the pins down. This can be done on one side (right or left) of the chip if it only has two sides (like the MCU used in the ATS3B). I <http://www.flickr.com/photos/lotts-family/2899887785/in/set-72157601974674441/> sweep the air over the pins on both sides but focus mostly on the side that I am wedging. That way the other side is nearly ready to go when the first side gives. It happens real fast if you have wicked the solder to begin with. Quad sided devices (none on the ATS3B) don't give up one side.. its all or nothing. I would still pry at a corner while sweeping the hot air all around the pins if I had a single <http://www.flickr.com/photos/lotts-family/2898796106/in/set-72157601974674441/> jet nozzle. I have special nozzles for my hot air rework <http://www.flickr.com/photos/lotts-family/2898777750> station that actually shoot <http://www.flickr.com/photos/lotts-family/2900670030/in/set-72157601974674441/> air on all pins at the same time without heating the chip for that occasion.

Great information, just great. You always put so much effort and care into your detailed posts, I really appreciate it. I especially like your photos, of course. A picture is worth a thousand words.

One technique I'd like to try for removing SMD's is to use thin stainless steel shim stock or feeler gage leaves (super thin sheet metal, thinner than tin or aluminum foil, but much stiffer, like a razor blade) to slide under the contacts of devices as soon as the solder softens. I haven't tried it yet, but I don't think solder will stick to stainless steel, so I can separate the pins of a device from the board at the precise moment the solder reaches it's melting temperature, and no hotter. Plus, I don't have to melt all the pins at the same time, since the shim physically blocks each pin from rebonding with the pads on the board.

It's been a long time since I've done any SMT soldering, but if I remember correctly, with practice I was able to solder and remove components so quickly and easily that they would only be warm after the process was complete. I've never damaged a component with heat before.

I'm getting pretty excited about this, maybe I'll have to quit talking and start doing. All in due time.

I should have stated more clearly that I wedge the plastic body.. not the pins

From: AT_Sprint@yahoogroups.com [mailto:AT_Sprint@yahoogroups.com] On Behalf Of ken Lotts (at home)
Sent: Friday, November 07, 2008 11:22 AM
To: AT_Sprint@yahoogroups.com
Subject: RE: [AT_Sprint] Re: Butane Soldering Iron For SMT SMD work

This only applies to multi pin devices.. simple SMD parts like resistors and capacitors etc can USUALLY just be blown off with the air nozzle. The idea is not damaging the board so always keep an eye on the temperature and exposure time.
The term "Wedge" refers to the action of prying the chip away from the board.

Wedge the blade so that it applies a force that will pop the device away from the circuit board once the solder is no longer firmly holding the pins down. This can be done on one side (right or left) of the chip if it only has two sides (like the MCU used in the ATS3B). I <http://www.flickr.com/photos/lotts-family/2899887785/in/set-72157601974674441/> sweep the air over the pins on both sides but focus mostly on the side that I am wedging. That way the other side is nearly ready to go when the first side gives. It happens real fast if you have wicked the solder to begin with. Quad sided devices (none on the ATS3B) don't give up one side.. its all or nothing. I would still pry at a corner while sweeping the hot air all around the pins if I had a single <http://www.flickr.com/photos/lotts-family/2898796106/in/set-72157601974674441/> jet nozzle. I have special nozzles for my hot air rework <http://www.flickr.com/photos/lotts-family/2898777750> station that actually shoot <http://www.flickr.com/photos/lotts-family/2900670030/in/set-72157601974674441/> air on all pins at the same time without heating the chip for that occasion.

Re: Butane soldering irons vs. torches

I may not have made it clear that used the RS butane soldering IRON, not a torch. It works just like an electric iron for the classic "one joint at a time" method. Lightly tin one pad, lay the part on with tweezers, hold it down, reheat that joint, solder other pin(s) of the part, revisit first joint as needed.

I haven't tried using the torch as a heat gun for the solder-paste method. (I have used the hot-air embosser. It is so cheap and works so well I'm not looking for an alternative.)

For unsoldering multi-pin devices, I think KD1JV suggests this trick. Thread some fine enameled wire under the pins where they angle out from the plastic package, and anchor one end (perhaps by soldering to a convenient point on the board). Apply a gentle pull to the side as you reheat the pins. The wire will sweep under each pin as it gets hot enough and separate it from the PCB. Repeat for the other row(s) of pins I did have to unsolder a part -- can't remember if it was the MCU or the DDS that I carefully soldered in backwards -- and this method worked great.

> Have you considered just designing a new circuit board?

Sorry, Ken, I do not plan to do do that. I simply do not have time to master circuit board design. I tried it once or twice, but for most of my circuit design it is much faster to use Manhattan construction or perfo board.

I plan to publish circuit diagrams and firmware though. Anybody is free to design circuit board from it. My estimate is that you would need smaller vias and probably four layer board with ground plane in the middle to fit all the circuits on the Altoids tin format board. It is perfectly doable, only the board would be lot more expensive.

I have a small field soldering iron that works with three AA cells. It works fine with through hole parts, but I did not try it with SMD components. I guess the butane iron gives more heat - I have only used torches before.

I invested to new technology and bought a new SMD hot air rework station with temperature control. It can do the classical soldering work too, though the area you are heating is a little larger than the tip of a soldering iron. You can use different sizes of nozzles to spot the heat. The hot air tool is very handy for removal of the SMD components and you can use it also with different plastics.

Topic: 3764 Message: 3790

I have used a Portasol butane soldering pencil for the majority of my kit assemblies until buying a temp controlled unti. I used the 1 mm Portasol tip for the ATS 2 and ATS 3. Where more heat is required on the ground side, I used the next larger tip or turned up the heat. You can adjust the heat and board burning and trace lifting are almost eliminated with experience. The catalytic ports on the tip put out more than enough heat to apply shrink tubing. I recently used the Portasol to solder a number of PL-259s outside when fixing my Gap antenna - I had to use the largest Portasol tip to get enough heat.

The tips can be a little pricy.

One does have to have a ready supply of butane (I buy the inexpensive imported stuff) and extra tips (they break due to heat/metal fatigue). Also, I do not have a rest so I rest the tip over the edge of the assembly table - usually I solder 5 or six parts and then turn off the unit. The unit heats up quite quickly to soldering temperature - you get to know the right setting. If when soldering you need more heat, you just dial up more heat.

Overall, I have been pleased with the units (I have an old and new style) and have not destroyed a part or board yet. I have also used the Radio Shack unit but I only have the one tip that came with the unit.

Hi gang.

I updated following page with high resolution images of my extended ATS-3b. I borrowed a tiny pocket digital camera and I just wonder how far the development of CCD sensors went in 7 years since I bought my first digital camera. The new CCD chip, even if it has 4x more pixels, seems to be more sensitive than the old low resolution one. Also I am terrified how dirty my board is. It seems that trying to clean it with rubbing alcohol only dissolved the flux to let dust stick firmly.

I think he might want some change ;-)

Here is my working list... feel free to add to it:

First..
Important stuff that needs to stay real close to the same:
-Altoids size
-Power consumption & weight

changes =(within reason)= that I would like to see

Firmware changes..
-chirp tuning to save batteries & finals (this is only firmware)
-step size memory for scan feature (scan works best with 10hz step)
-cw speed indicator
-Enhance keying (variable parameters)
-I hate cryptic menus as much as the next guy but If embedded menu functions become an issue, make an *option* to disable or simplify them.

hardware changes:
-swr indicator (maybe that only fires up in the tune mode?)
-variable bandwidth filter (or bypass like the ats3)
-built in touch keyer circuit
-SPY bi-wire vs jtag (MSP430F2132?)

I think there are mods to make the more robust PA. See the PFR-3 for details.

That's interesting. Did you ever try using the heat blower on SMT SMD's?

--- In AT_Sprint@yahoogroups.com, Full Some <full.some@...> wrote:
>
> I have used a Portasol butane soldering pencil for the majority of my kit assemblies until buying a temp controlled unti. I used the 1 mm Portasol tip for the ATS 2 and ATS 3. Where more heat is required on the ground side, I used the next larger tip or turned up the heat. You can adjust the heat and board burning and trace lifting are almost eliminated with experience. The catalytic ports on the tip put out more than enough heat to apply shrink tubing. I recently used the Portasol to solder a number of PL-259s outside when fixing my Gap antenna - I had to use the largest Portasol tip to get enough heat.
>
> The tips can be a little pricy.
>
> One does have to have a ready supply of butane (I buy the inexpensive imported stuff) and extra tips (they break due to heat/ metal fatigue). Also, I do not have a rest so I rest the tip over the edge of the assembly table - usually I solder 5 or six parts and then turn off the unit. The unit heats up quite quickly to soldering temperature - you get to know the right setting. If when soldering you need more heat, you just dial up more heat.
>
> Overall, I have been pleased with the units (I have an old and new style) and have not destroyed a part or board yet. I have also used the Radio Shack unit but I only have the one tip that came with the unit.

Hi Ken.

> -chirp tuning to save batteries & finals (this is only firmware)

This is a simple one. Actually in OK land I was told one shall send Vs during antenna tuning.

> -cw speed indicator

Would you be more specific?

> -Enhance keying (variable parameters)

What do you want to configure? I think one shall send a perfectly timed morse code to be understood well, which is of high importance with QRP levels. I understand parameters like dash/dot ratio settnings to be useful for transmitter chains, where the mark is shortened by RX/TX relay. But with solid state BK there is IMHO no need for such settings.

What I find useful (and there is still space in FLASH) is to add AccuKeyer auto space feature and a mode simulating single lever paddle with iambic paddle. I will try to do that with "my" firmware.

> -I hate cryptic menus as much as the next guy but If embedded menu functions
> become an issue, make an *option* to disable or simplify them.

Would you please explain that? I am working on "my" firmware right now, so any idea will be appreciated.

> -swr indicator (maybe that only fires up in the tune mode?)

Well, a SWR bridge will take considerable space in the Altoids box. Otherwise it would not be difficult if you have two controller pins with A/D function available. Finally I decided NOT to put it into my device mostly because of space constraints, but also because of controller pins available (and because I am using Elecraft T1, which has SWR bridge built in). Anyway, if you want to do it, go ahead with the display driver mod, for illustration see the pictures, here is the link again. The firmware change to send to shift register instead of directly to display is not difficult.

http://www.kufr.cz/~ok1iak/HAM/ATS3b/index.php3

> -variable bandwidth filter (or bypass like the ats3)

My solution with D/A converter, Op Amp and 2 transistors to create weak current voltage source from 0 to full battery voltage to control varactors in IF filter is probably overkill for such a tiny radio. Elecraft is on purpose powering the whole digital part in K1 with 6V, which will open the IF filter up to 800Hz. My solution will open the filter wider with higher battery voltage. Elecraft KX1 tunes IF filter with analog pot sourced from 6 volts. The maximum catalog bandwidth of KX1 is 2kHz, which is IMO wider than K1 only

because KX1 has less selective IF (3 crystals instead of 4).

If you want to go simple, I would recommend to go to http://www.danssmallpartsandkits.net/ and buy three of MVAM109. Quite pricey though. Replace the three shunt capacitors in IF filter with the varactors. Build a tiny SPDT switch into the box, must really throw before make. Switch between full battery voltage after the hot carrier diode and 3.5V stabilized voltage, use that to bias the varactors. You will get a switchable bandwidth between about 300Hz and 1.5kHz. The filter shape at 1.5kHz will not be pretty though.

If you are willing to buy from oversees, try ordering 3KB313 at
http://www.elektronika.cz/inshop/scripts/set.asp?Level=420
These are the parts I am using in my ATS-3b. You may send a request to info@... .
The parts are surplus from cold war era. Three paired varactors are sold for about 60 cents without packing and shipping. Maybe a group buy would be worth, before they sell out.

> -built in touch keyer circuit

Buy two of QT113, DigiKey #427-1138-1-ND. Glue it to the top side of the ATS-3b board, wire it according to the datasheet. It seems Quantum Research was bought by Atmel.

> -SPY bi-wire vs jtag (MSP430F2132?)

What will be the benefit?

Mark K5LXP wrote:

> 4 layer board.

This is a means not requirement on its own. 4 layer board is more expensive and it is also harder to trace if something goes wrong. I would go with 4 layer board only if necessary.

Hank Greeb wrote:

> I think there are mods to make the more robust PA. See the PFR-3 for details.

I looked at the PFR-3 schematic and there is no essential difference between ATS-3b and PFR-3 PA. The FETs in ATS-3b are 2n7000, in PFR-3 BS170, which are slightly more robust, but essentially very much equivalent transistors.

I compared the ATS-3b/PFR-3 PA design with NorCal 2030. NorCal 2030 has overvoltage protection by measuring the peak voltage and closing PA driver. ATS-b3 just dumpens the spikes with 47V Zener diode. NorCal 2030 measures PA current and if it is too high, it limits PA driver. ATS-3b over current protection resets CPU, which may be annoying, but it has two reasons.

1) There is no controller pin available for over current protection sense in ATS-3b.
2) If controller goes havoc and leaves DDS pin16 low and MSP430 pin 24 high, the three 2n7000s in PA will burn in couple of seconds. I believe it happened to me with ATS-3a once during firmware debugging.

Actually this danger would be mitigated by putting 100nF cap between PA gates and driver as done in NorCal 2030 or Steve's special PSK31 transmitter.

I released controller P3 pins by using shift register to drive the display. Now I am using port 3 for following pins.

1 pin for shift register clock
2 pins for rotary encoder
2 pins for I2C bus (SDA, SCL)
1 pin to switch AF filters (CW/SSB)

I still have two pins left for other purposes. I will most probably use them for current sensing and peak RF sensing or PA voltage sensing or PA temperature sensing. Not exactly RF bridge, but it will allow one to calculate PA input power and will allow experimenting with more reasonable PA over current algorithms.

Vojtech,

Thanks for the reply!

I have only a few minutes so I can only do a partial reply right now..

Ø This is a simple one. Actually in OK land I was told one shall send Vs during antenna tuning.

I am thinking that in reality, there are times when everyone resorts to a low power dead key as they struggle with difficult tuning situations in a field environment (and does a station ID at the end of course). The ATS3 even has a dead key tune position in its menu. There is no power adjustment so it is either full power or nothing.. given the choice of a full power dead key or a full power low duty cycle rapid pulse, I would choose the later every time (its easier on the finals and the battery). I would not eliminate the dead key feature, I would just add another choice..

I have an MFJ device that does this at 75WPM, 13% duty cycle and I find it to be wonderful.. That is why I would like to see this as an option in the ATS3X rigs..

I have never looked at and measured the pulses on a scope.. maybe I will get things set up if you are interested.

Vojtech,

Lunch hour is here so I am responding to another of your questions..

>> -I hate cryptic menus as much as the next guy but If embedded menu functions become an issue, make an *option* to disable or simplify them.

Ø Would you please explain that? I am working on "my" firmware right now, so any idea will be appreciated.

The menus...

This whole topic has merit only after you pack too many user configurable options in the menu system.. Right now, maybe the menus are not so bad, but if much were to be added, then this could be a big deal. The MSP430 can do a lot especially if the next version moves to one with more room..

I have not really come up with an exact menu configuration but I can explain the concept of what I was thinking.

Look at most any computer program that has drop down menus.. The drop down selections can be abbreviated unless they are needed.. that is the concept. Just like the VFO toggles from A to B (in W1MT firmware), you could toggle menus from simple to advanced (with adequate feedback),

Ideally a user could custom configure the firmware to clump certain commands into either category (more options HI)

In a Morse menu system, divide and conquer can be a good starting point..

One of my commercial devices does this by having an inquiry and a command mode. Basically, in that device, to trigger the inquiry mode, you simultaneously press two buttons and it responds with a question mark. You answer the question mark with a single letter response.. For example, the letter "S" would tell the device that you would like to know the current morse speed setting. In that world, you actually communicate with the device rather than marching through a menu. You enter the command mode and give it single letter and parameter instructions, you enter the inquire mode and ask it single letter questions...

Vojtech,

Thanks for the reply!

I have only a few minutes so I can only do a partial reply right now..

Ø This is a simple one. Actually in OK land I was told one shall send Vs during antenna tuning.

I am thinking that in reality, there are times when everyone resorts to a low power dead key as they struggle with difficult tuning situations in a field environment (and does a station ID at the end of course). The ATS3 even has a dead key tune position in its menu. There is no power adjustment so it is either full power or nothing.. given the choice of a full power dead key or a full power low duty cycle rapid pulse, I would choose the later every time (its easier on the finals and the battery). I would not eliminate the dead key feature, I would just add another choice..

I have an MFJ device that does this at 75WPM, 13% duty cycle and I find it to be wonderful.. That is why I would like to see this as an option in the ATS3X rigs..

I have never looked at and measured the pulses on a scope.. maybe I will get things set up if you are interested.

Hi Ken.

> -chirp tuning to save batteries & finals (this is only firmware)

This is a simple one. Actually in OK land I was told one shall send Vs during antenna tuning.

> -cw speed indicator

Would you be more specific?

> -Enhance keying (variable parameters)

What do you want to configure? I think one shall send a perfectly timed morse code to be understood well, which is of high importance with QRP levels. I understand parameters like dash/dot ratio settnings to be useful for transmitter chains, where the mark is shortened by RX/TX relay. But with solid state BK there is IMHO no need for such settings.

What I find useful (and there is still space in FLASH) is to add AccuKeyer auto space feature and a mode simulating single lever paddle with iambic paddle. I will try to do that with "my" firmware.

> -I hate cryptic menus as much as the next guy but If embedded menu functions
> become an issue, make an *option* to disable or simplify them.

Would you please explain that? I am working on "my" firmware right now, so any idea will be appreciated.

> -swr indicator (maybe that only fires up in the tune mode?)

Well, a SWR bridge will take considerable space in the Altoids box. Otherwise it would not be difficult if you have two controller pins with A/D function available. Finally I decided NOT to put it into my device mostly because of space constraints, but also because of controller pins available (and because I am using Elecraft T1, which has SWR bridge built in). Anyway, if you want to do it, go ahead with the display driver mod, for illustration see the pictures, here is the link again. The firmware change to send to shift register instead of directly to display is not difficult.

http://www.kufr.cz/~ok1iak/HAM/ATS3b/index.php3

> -variable bandwidth filter (or bypass like the ats3)

My solution with D/A converter, Op Amp and 2 transistors to create weak current voltage source from 0 to full battery voltage to control varactors in IF filter is probably overkill for such a tiny radio. Elecraft is on purpose powering the whole digital part in K1 with 6V, which will open the IF filter up to 800Hz. My solution will open the filter wider with higher battery voltage. Elecraft KX1 tunes IF filter with analog pot sourced from 6 volts. The maximum catalog bandwidth of KX1 is 2kHz, which is IMO wider than K1 only because KX1 has less selective IF (3 crystals instead of 4).

If you want to go simple, I would recommend to go to http://www.danssmallpartsandkits.net/ and buy three of MVAM109. Quite pricey though. Replace the three shunt capacitors in IF filter with the varactors. Build a tiny SPDT switch into the box, must really throw before make. Switch between full battery voltage after the hot carrier diode and 3.5V stabilized voltage, use that to bias the varactors. You will get a switchable bandwidth between about 300Hz and 1.5kHz. The filter shape at 1.5kHz will not be pretty though.

If you are willing to buy from oversees, try ordering 3KB313 at
http://www.elektronika.cz/inshop/scripts/set.asp?Level=420
These are the parts I am using in my ATS-3b. You may send a request to info@... <mailto:info%40fanda.cz> .
The parts are surplus from cold war era. Three paired varactors are sold for about 60 cents without packing and shipping. Maybe a group buy would be worth, before they sell out.

> -built in touch keyer circuit

Buy two of QT113, DigiKey #427-1138-1-ND. Glue it to the top side of the ATS-3b board, wire it according to the datasheet. It seems Quantum Research was bought by Atmel.

> -SPY bi-wire vs jtag (MSP430F2132?)

What will be the benefit?

Mark K5LXP wrote:

This is a means not requirement on its own. 4 layer board is more expensive and it is also harder to trace if something goes wrong. I would go with 4 layer board only if necessary.

Hank Greeb wrote:

> I think there are mods to make the more robust PA. See the PFR-3 for details.

I looked at the PFR-3 schematic and there is no essential difference between ATS-3b and PFR-3 PA. The FETs in ATS-3b are 2n7000, in PFR-3 BS170, which are slightly more robust, but essentially very much equivalent transistors.

I compared the ATS-3b/PFR-3 PA design with NorCal 2030. NorCal 2030 has overvoltage protection by measuring the peak voltage and closing PA driver. ATS-b3 just dumpens the spikes with 47V Zener diode. NorCal 2030 measures PA current and if it is too high, it limits PA driver. ATS-3b over current protection resets CPU, which may be annoying, but it has two reasons.

1) There is no controller pin available for over current protection sense in ATS-3b.
2) If controller goes havoc and leaves DDS pin16 low and MSP430 pin 24 high, the three 2n7000s in PA will burn in couple of seconds. I believe it happened to me with ATS-3a once during firmware debugging.

Actually this danger would be mitigated by putting 100nF cap between PA gates and driver as done in NorCal 2030 or Steve's special PSK31 transmitter.

I released controller P3 pins by using shift register to drive the display. Now I am using port 3 for following pins.

1 pin for shift register clock
2 pins for rotary encoder
2 pins for I2C bus (SDA, SCL)
1 pin to switch AF filters (CW/SSB)

I still have two pins left for other purposes. I will most probably use them for current sensing and peak RF sensing or PA voltage sensing or PA temperature sensing. Not exactly RF bridge, but it will allow one to calculate PA input power and will allow experimenting with more reasonable

PA over current algorithms.

I believe that K1EL keyers work this way. I have a K12 around here somewhere. At one point I was considering implementing this in my firmware but the code space was too tight at the time. Now that this newer chip has twice the space it may be doable... Could make the interface much more simple, although one might be definitely dependent on a cheat sheet. Might be worth revisiting...

Hi Steve.

I have Jornada 720 too. It is a nice device. It has essentially the same hardware as iPaq 3630, only twice as big screen and 3/4 size keyboard. I bought my device with cracked display hinge for about $50. Jornada 720 runs on two LiIon cells and mine runs much longer than the iPaq 3630.

If you want to run it with ATS3B, you will need to build the slicer. It's sound output is too weak to drive paddle input directly.

I have been playing with the challenge of combining my ATS-3a and QBSA in a single enclosure. I settled on the LMB Crown Royal CR-332-P (Mouser 537-CR-332). Its dimensions are 3.75 L x 3.00 W x 2.13 H. Chuck W5USJ often recommends these things. They are nice looking with the bottom painted white and the top blue. When I received the enclosure, I found that the two units did fit into it, but snugly. I thought I would mount the QBSA in the bottom with the frequency read-out on the front panel and put the ATS-3a on the bottom-side of the top of the cover, radio bottom-side (switches) up. Then I remembered the band filter modules. I would have to open the enclosure each time I wanted to change bands. Since the enclosure is buttoned up with small sheet metal screws, changing bands would be annoying. I wonder if there is something I could substitute for the screws that would perform as a quick-release fastener. I also have a Bud enclosure of somewhat larger size that has little punched out, nipple-like convexities on the sides of the top and corresponding holes on the flanges of the bottom (I got it from Mouser, but I've lost track of the stock number). This enclosure is much uglier than the Crown Royal, but the top is easily removed by squeezing the sides and lifting. I'm hesitating, because I really prefer the Crown Royal enclosure. Any suggestions would be greatly appreciated. 72, Dave K1YHR.

Vojtech,

Thanks for the cool info on the SWR bridge and filter! To be honest I was looking at much more primitive solution for both. A simple resistive bridge and a mini relay controlled from the MCU would be good enough for me and I really liked the total filter bypass that was in the older ATS3. Heck regarding space, there is room for daughter cards.. even so much that I think it might be possible (with some creative imagination) to design a set of normal 2-layer boards that would host your current highly modified ATS3X within an Altoids.

Regarding the touch circuit.. Yup! you have the right idea. This is such a popular mod that I think it at some point should just be integrated into the board.

As far as the JTAG.. I don't know.. I have had various degrees of success and failure with being able to actually run debug via the JTAG. My new FET (MSP-FET430UIF) programs via the JTAG just fine but I cant leave it connected or else the rig wont respond to the buttons or the key paddles. I really don't know that things would improve with the spy bi-wire but one thing for sure is that the footprint of the header would be a lot smaller (HI) and it would be easy to run it to the outside. The down side on that one is that it would make it less practical to field program unless you had spy bi-wire FET.

As far as the keying parameters... Well, I am not a super accomplished morse man so I wont even begin to take a stand on what should and what shouldn't be except to say that the ATS rigs focus on CW therefore the keyer functionality is at the bulls eye heart of what's really happening. I will play around with settings forever until I settle in to something that feels right. I am thinking that the more customizable the feel of the keyer the happier the owner..

You really wrote a lot of stuff.. I appreciate the all of the info. If I missed something let me know.

Thanks again

Vojtech,

Lunch hour is here so I am responding to another of your questions..

>> -I hate cryptic menus as much as the next guy but If embedded menu functions become an issue, make an *option* to disable or simplify them.

? Would you please explain that? I am working on "my" firmware right now, so any idea will be appreciated.

The menus...

This whole topic has merit only after you pack too many user configurable options in the menu system.. Right now, maybe the menus are not so bad, but if much were to be added, then this could be a big deal. The MSP430 can do a lot especially if the next version moves to one with more room..

I have not really come up with an exact menu configuration but I can explain the concept of what I was thinking.

Look at most any computer program that has drop down menus.. The drop down selections can be abbreviated unless they are needed.. that is the concept. Just like the VFO toggles from A to B (in W1MT firmware), you could toggle menus from simple to advanced (with adequate feedback),

Ideally a user could custom configure the firmware to clump certain commands into either category? (more options HI)

In a Morse menu system, divide and conquer can be a good starting point..

One of my commercial devices does this by having an inquiry and a command mode. Basically, in that device, to trigger the inquiry mode, you simultaneously press two buttons and it responds with a question mark. You answer the question mark with a single letter response.. For example, the letter "S" would tell the device that you would like to know the current morse speed setting. In that world, you actually communicate with the device rather than marching through a menu. You enter the command mode and give it single letter and parameter instructions, you enter the inquire mode and ask it single letter questions...

Hello everyone!

Hard to believe that it's the 3rd Sunday in November already! Before you know it, Thanksgiving will be upon us. So we have something for you to be "pre-thankful" for. It's RFTB weekend!.

The Flying Pig's monthly "Run For the Bacon" QRP CW contest is this Sunday night! After a long day of raking leaves and cleaning gutters take some time for yourself to enjoy QRP and Amateur Radio.

This friendly, low pressure, 2 hour sprint runs from 9:00 to 11:00 PM Eastern Standard Time.

For all the details, please visit http://www.fpqrp.com/fpqrprun.php

The Flying Pigs QRP ARCI is now maintaining an archive of previous "pig-runs" for your viewing pleasure.

See you in the troughs!

The word "slicer" is generally used for a circuit, which converts analog signal into digital one by thresholding. The threshold may be fixed or floating based on some kind of averaging, or the threshold may have hysteresis. Whatever works for that kind of signal.

3825. NAQCC Sprint Wednesday night!

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-11-17 02:45:51 UTC
From: NAQCC
Topic: 2848 Message: 3825

NAQCC Sprint Wednesday night!
This coming Wednesday evening will be the monthly NAQCC Sprint for November, 2008.

I will refer you to the proper URL:

http://www.arm-tek.net/~yoel/sprint200811.html

There you will find all the details as to time, frequencies and also a special prize.

This month's Special Award goes to the winner of a drawing among the following: The one making the highest score in each division and using a homebrew key or bug they made themselves. Note that you must have made it all by yourself from scratch. It can't have been made by someone else.

This is a monthly event that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate (this includes QRO); but you must use QRP power levels to compete for awards.

Come join us and have a real good time!

73 de Dave VA3RJ
NAQCC #0004

3826. Re: [AT_Sprint] Re: Butane Soldering Iron For SMT SMD work

Yahoo group: AT_Sprint (2002 — 2008)

Topic: 3764 Message: 3826

TimI never tried it. Interesting thought; however, the narrow field of heat might only allow a couple of smt parts to be "soldered" at a time. But, this might be good where one is desoldering an individual part as all contacts would be heated allowing for fairly easy removal - this could be an alternative to the two soldering iron technique.

That's interesting. Did you ever try using the heat blower on SMT

SMD's?

--- In AT_Sprint@yahoogrou ps.com, Full Some <full.some@. ..> wrote:

>

> I have used a Portasol butane soldering pencil for the majority of

my kit assemblies until buying a temp controlled unti. I used the 1

mm Portasol tip for the ATS 2 and ATS 3. Where more heat is

required on the ground side, I used the next larger tip or turned up

the heat. You can adjust the heat and board burning and trace

lifting are almost eliminated with experience.   The catalytic ports

on the tip put out more than enough heat to apply shrink tubing. I

recently used the Portasol to solder a number of PL-259s outside when

fixing my Gap antenna - I had to use the largest Portasol tip to get

enough heat.

>

> The tips can be a little pricy.

>

> One does have to have a ready supply of butane (I buy the

inexpensive imported stuff) and extra tips (they break due to heat/

metal fatigue). Also, I do not have a rest so I rest the tip over

the edge of the assembly table - usually I solder 5 or six parts and then turn off the unit. The unit heats up quite quickly to soldering temperature - you get to know the right setting. If when soldering you need more heat, you just dial up more heat.

>

> Overall, I have been pleased with the units (I have an old and new style) and have not destroyed a part or board yet. I have also used the Radio Shack unit but I only have the one tip that came with the unit.

I followed your suggestion and picked up a Jornada 720. Now I have to figure out how to load pocket digi. I've tried to use active sync to load it but the PC and J720 won't link.

I'm going to try to copy the files (.cab. inin and .dat) to a cf card and then install from there.

Any suggestions will be appreciated. Thanks. Steve

No problem with the OT post, but I've been advised by a whole bunch of people to avoid the "grouply" grouping of yahoo groups for various reasons, which I won't go into here. If anyone wants to know the reasons, I'll dig up the messages and forward them privately.

I copied the files to a CF card. Mounted it in the J720 and then
double clicked on the .cab file. It seemed to install the
program...however...when I tried to execute the program, it says pops
a window that says "Cannot find 'PocketDigi' or one of its components.
Any help? Thanks Steve

Hi Steve.

I would just copy the exe file to compact flash and start it from there.
Download the PocketDigi-1.0.0.11-arm.zip and extract the PocketDigi-hpc.exe file to compact flash. Make sure you are not running the non-hpc executable on your handheld pc device. It will not work.

The installer was created by Patrick N0HR and he did not test it on handheld pc, so it most probably does not work. I would advice you to deinstall Patrick's installer first.

Vojtech,
I downloaded the PocketDigi_1_0_11.exe to my PC. I unpacked it and got the folowing 4 files:

PocketDigi.ini
PocketDigi_PPC_MIPS 4000.cab
PocketDigi_PPC_StrongARM.cab
suninstall.dat

I copied the PocketDigi_PPC_StrongARM.cab to the CF and moved it to the J720.

I executed the file and it installed an application into the \Program Files\Pocketdigi folder. The application is 263KB and is dated 1/6/08 2:39:32 PM.

When I execute the application I get the "Cannot find 'PocketDigi or one of its components message.

Help. Steve

Hi Steve.

I do not know what the installer does and I suppose that it was not tested on Jornada.
Simply deinstall it and copy the executable manually.

Download PocketDigi-1.0.11-arm.zip and unzip it on your PC.
Copy PocketDigi-hpc.exe on your flash card.
Start PocketDigi-hpc.exe from flash card on your Jornada 720.

I did a search for the file name you sent me. When I found it I downloaded it and copied it to the CF card. It worked. Now to heat up the soldering iron and build the interface. Thanks for all your help. Steve K2ZPF

3838. Simple Digital Interface not working on iPAQ 2210

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-12-02 02:02:04 UTC
From: Andreas Burkart
Topic: 3838 Message: 3838

Folks,

I finished my ATS - 3B a little while ago and built the simple interface cable to connect it to my IPaq 2210. While the PocketDigi on the Ipaq works flawlessly with the built in microphone attached to the ATS3-B head phones or my Kenwood TH6 loudspeaker, it simply does not work with the simple digital interface cable in digital mode. I modified the cable and took out the two 1K resistors on the PC side and tried the iPAQ and my laptop --> unsucessfully.

It seems that two things are happening here:

1. When I attach the cable to the ATS-3B , the ATS-3B picks up noise from the IPAQ (it gets worse, when the power adapter is connected to ththe iPAQ)

2. It seems that the two 1K resistors are not switching off the internal microphone of the iPAQ, and ambient noise is being picked up (pencil drop etc.)

3. There is only noise on the waterfall screen but no clear line even with strong CW signal in the head phone

I exhausted all possible settings on IPAQ and Pocketdigi.

I selected the iPAQ 2210 because of the built in microphone and 3.5 mm audio input.

I wonder if you could help me further trouble shooting.

Would the sound card interface cable work better ?

P.S. the CAT function worked for a little while but stopped altogether.

Andreas,

To check the simple things first, are you putting the ATS3B into Digital Mode before connecting the cable?

I do not wonder that ATS is picking noise from the switched power supply. Run it on internal battery.

> P.S. the CAT function worked for a little while but stopped
> altogether.

The simple interface requires quite high amplitude from your iPaq. You will have to crank up sound volume to maximum or nearly maximum. Try to experiment. It may happen, that the amplitude from your iPaq is just on the threshold to trigger the schmitt inputs in ATS. You may confirm it by trying to connect ATS through the simple interface to your PC. Also do not forget to switch off sound notifications on your iPaq, otherwise they will interfere with the data sent over the simple interface.

Hi Andreas,

I suspect that Vojtech's advice to you is probably the best, since he is
the one who made digital mode possible on the ATS rigs. Can get the
digital mode to work on a regular computer?

> Will this iPAQ suffice for digital mode operation with my ATS3B?

I wonder what is the difference between 3630 and 3650. PocketDigi was developed mainly on iPaq 3630.
The biggest problem of the device is high backlight current and bad battery management. If you forget your device uncharged for an extended period of time, the battery will be undercharged and will deteriorate badly. Htere is a small slide switch on the bottom to disconnect battery if you are not going to use the device for months. Otherwise it is a reasonable device for the price.

3846. Wider audio on 3B - Anyone done it?

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-12-04 18:15:20 UTC
From: mpupeza
Topic: 3846 Message: 3846

Hi,
I'd like a wider audio on my 3B! The narrow noise sounds almost like ringing to my ears, whereas I can tolerate my IC-703 at 500Hz bandwidth a lot better!
I know that Steve suggested that C5, C6, and C7 in the crystal filter 'could' be lowered for a wider response.
Has anyone tried this? What values worked best and what was the BW?
My 3B is about 200Hz at -6 dB presently!
The good part is that the caps are on the display side of the rig, so I can change them without as much hassle!
I'd have to order up some caps, so having an idea of values would be a big step ahead!
Thanks for any help.

I replaced the three caps with varactors and I tune bandwidth from zero to about 1.5kHz. At wider bandwidths the response is not flat. The minimum capacity is about 27pF at widest bandwidth.

If you want to get flat response at wider bandwidth, you would need to experiment with input and output termination also.

Vojteck;
If you were to select around 400-500 Hz bandwidth, and reasonably flat, what capacitors would you suggest for c5, c6 and c7?
I've ordered up a kit of SMD 805 Caps (and resistors) so should have the standard values. I was going to try 100 pF or the next smaller to start. I really just want to 'smooth' out the background noise, and am not a fanatic about narrow selectivity nor ultimate 'flatness'!
Thanks,
Mike VE3EQP/W4 .....>

Just posted photos of the ATS work/maintenance station at KT6L. Located in the "reading/music/tv" room of the house, the paint pan and panavise make assembly/maintenance easier and more comfortable.

The green lead attached to the paint pan is connected to a dedicated 3 pin plug that helps to
reduce probability of static charge build-up and damage. It really helps a lot using a large
wattage "daylight" lamp and large magnifier. I've killed bigger fleas on my dog than some of
the resistors and caps on the "3B."

NAQCC Sprint Tuesday night!
This coming Tuesday evening will be the monthly NAQCC Sprint for December, 2008.

I will refer you to the proper URL:

http://www.usatek.net/~yoel/sprint200812.html

There you will find all the details as to time, frequencies and also a special prize.

This month's Special Award goes to the winner of a drawing among the highest scorers from each division who are able to make the word 'CHRISTMAS' from the calls of stations they work. Note: you only need to work one station with a letter "S" to get your two "Ss".

This is a monthly event that caters to the CW veteran, the CW newcomer, straight key and bug fans. All are welcome to participate (this includes QRO); but you must use QRP power levels to compete for awards.

Come join us and have a real good time!

Topic: 3853 Message: 3853

I'm working on it. Just ordered the main board today, next will be the filter boards. Then I guess I will have to start collecting the parts.

Since the guy who was making my boards went belly-up this summer, I had to find a new place to get boards made. That gave me an excuse to make some minor changes. I switched to using BS-170's for the PA, as they seem to be holding up well in the PFR-3 rigs. This change eliminated the need for the over current detector, so those parts have been taken out.

I was able to make room for 0805 resistors to replace the 0602 ones. No one seemed to have much trouble with the 0602 sized parts, but they were a pain. I also moved the LED display a little farther away from the switches.

That's all I could do. I know there was quite a list of things some of you wanted added to the rig, but those things are not possible without making the board larger, making the layout a nightmare and increasing the price. If anything, I wanted to make the price less, which I'm going to do. I hopeing for $175.00 in light of the current economic meltdown, assuming there are no suprises in the price of the rest of the parts.

I was thinking of cutting costs even more by eliminating the LED display (which would have allowed going back to a less expensive MPU) and going back to 4 bands instead of 6. But in the end, I decided that these cost cutting measures weren't worth it.

So, if your still waiting to get one of these rigs,(and since I belive there are more members in this group than the number of rigs made so far, thats a good bet), in about another month they should start to be ready.

72, Steve KD1JV

Last month I finally got around to assembling my second 3B which came from the last run. I was having trouble with the solder paste from Cash Olsen being too dry so I bought some locally. Though it cost three times as much, I was able to get those nice little hershey drops of paste on the pads like in those videos on the web.

I did the board in five sections: the front side all at once, the back side in three sections. Then to complete I did all the backside semiconductors. Had the usual couple bridges on that IC with the close spaced pins! Touched-up some places where I did not use enough paste. All-in-all the hot air method was not too bad.

The biggest mistake I had was installing the reference oscillator backward. I found this during the initial checkout when I saw that I had no 3.3v. I ended up destroying it to remove it, obtained the part number from Steve, and got a replacement from Mouser. Once installed I got the friendly '8' greeting in the headphones and on the LED.

Today I did the calibration with no problems. I have not built the band modules yet, so I popped in the 20m module from my other 3B and heard some activity and registered a bit over 5 watts output into my NorCal Dummy Load, so the transmitter is working.

This second 3B is going to be a desktop version. I am waiting for the FCC-1 to become available again as it will be my frequency display. I will include an audio amp and speaker. I have built the rotary encoder in the files section for frequency tuning, but have not tried it yet. I also want to try and do externally attached band modules using edge card connectors.

Hopefully once it is all complete I can take some photos and post them.

I received a parcel from Mouser today with lot of parts for my next homebrewing. Among them there are some 3 digit LCD displays and bunch of 8bit shift registers. They will be used to build 3 digit display for my ATS-3b. Estimated price of all the parts at Mouser is about $2.60 for display and three 74VHC164M. The shift registers will be fed by the ATS's MCU. Additional current consumption will be less than one mA without backlight. If it works, it will be a blast.

If it works, I hope you will document it carefully and post it to the files section of the list. That would be great.

Thanks.

HI Steve,
Good to see you. One other addition to your list... us that have one of each of your designs....
and can't pass getting the next one too.. They each have their own personality and special place.
BTW, if you have someone that, say is a vet or physical reason for not being able to build your rig..
please feel free to pass along my name/call/address. I will build it for them, no charge.
Just happy to help them get a really nice radio, and be able to use the best.
Thank you,--... ...-- Dale - WC7S in Wy

The idea is to feed three 74HC164 8bit shift registers by two pins (data & clock). Only for clock an exclusive controller pin is needed, data pin may be shared with other devices, for example DDS. If backlight is needed, one needs other free controller pin.

LCD display needs to change polarity between backplane and all segments about 50x per second, otherwise the DC current will electrolyze the liquid crystals. This requires to feed the shift registers 50x per seconds. Not a problem for the ATS-3b controller. There will be some firmware changes necessary.

With Steve, it's always been "first come, first served". He does
not "do" waiting lists. It's just too much hassle to keep track of. He
also does not appreciate people sending money before something is
available.

Just stay tuned for further announcements.

Possibly off-topic:

I was wondering if there were more efficient heat sinks available that would help to protect
the PA in the ATS seriess - I remember seeing a derivation in one of my digital classes in college illustrating the heat build-up in a Pentium chip - the derivation and discussion took
over 15 minutes to show that over 1/2 the heat build-up was due to the capacitive reactance of the metal pads connected to the chip's silicon.

Hi Mike.

Based on my yesterday's experience, I would recommend you to build in a simple attenuator. You will find details in a word document from Milan OK1IF in group Files section. A 9mm 1k pot from Alpha is easily available at Mouser and fits well. Probably lower resistance like 330 or 470 Ohm pots will be better, but they are harder to find.

I wondered why the SSB sounds so harsh with wide IF filter and wide AF filter. I was essentially unable to understand the voice. Now I know. Something somewhere got overloaded. It may be the first mixer, second mixer, AF preamp, the clipping diodes in AF preamp or the AF AVC circuit. Maybe one day I will find out, but right now I don't know how to do it :-)

It makes a great difference to get rid of the IMD, receiving is much more pleasant. Adding an attenuator pot is the single most useful mod to this tiny rig.

3870. ATS3 Vs. Orion II

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-12-16 05:30:24 UTC
From: dyarnes1
Topic: 3870 Message: 3870

I was playing around (on a very noisy and barren 40 meter band) today, and decided to pull out my ATS3. That little rig hasn't had a workout for a few months now. Anyway, I was able to snag a couple of QSO's, with pretty decent reports too! Then I just listened around the band for about 30 minutes, and began comparing signal strengths between the ATS3 and my Orion II, using the same antenna. One station I ran across was particularly difficult to hear in the noise using the Orion II. When I switched over to the ATS3, I could actually copy that station better! Perhaps I was getting less noise in the ATS3 by running it off battery power, but it definitely could hear better. It was almost a matter of copying and not copying, since I wasn't really able to consistently hear the other station on the Orion II. This wasn't a very scientific comparison, but it certainly tells me that the ATS3 is a darn good little rig, and doesn't need to have many excuses given for it on receive.

I have two of these versions now, and I left one up in Oregon with my motorhome. I also have an ATS3B kit, which still needs to be built. I've been sidetracked multiple times from getting that done. I really enjoy pulling this thing out of my pocket at the ham breakfast gatherings. It's a real "gee whiz" type rig, which gets lots of scrutiny, but the best part is that it is a very serious radio! I think I just confirmed that, for the nth time, with my "A/B" test today with the Orion II. Next I'm going to try the same thing with my K3!

Dave W7AQK

3871. 3 digit lcd display prototype

Yahoo group: AT_Sprint (2002 — 2008)

From: Vojtěch Bubník
Topic: 3871 Message: 3871

Hi gang.

I wired the display on a piece of thin no copper laminate board with magnet wire. The circuit consists of three 74vhc164 shift registers and one schmitt trigger to clean up clock. The schematic is very much the same I already posted, only the schmitt trigger is missing. The total price for the display and shift registers was about $3.
http://ns.kufr.cz/~ok1iak/HAM/ATS3b/ats3b-display.gif

The faster shift registers (74vhc164, not 74hc164) were 2 cents cheaper at Mouser, so I ordered them, which was a big mistake. ATS controller generates too slow clock edges for these 130MHz capable chips. I had to clean the clock up with one schmitt trigger. I learned my lesson in digital circuits. I believe it would work without the schmitt trigger if one uses the regular slow 74hc164 chips.

Here is a short video (700kB) showing power on/off, frequency display and progressive tuning with the rotary encoder.
http://ns.kufr.cz/~ok1iak/HAM/ATS3b/ats3b-lcd-display.wmv

And here is one screenshot from the movie.
http://ns.kufr.cz/~ok1iak/HAM/ATS3b/ats3b-display.jpg

The display has no backlight, but lighting it up from the rear side through the laminate board with 3 LEDs using 10mA at 5V works reasonable, even though the backlight is not even without a good diffuser.

73, Vojtech OK1IAK

3872. OK1IF Attenuator Mod. Works Nice.

Run for the Bacon
Sunday December 21, 2008
6:00 pm - 8:00 pm
(This event repeats every month on the third Sunday.)
Location: Your shack or anywhere

Notes:
This Sunday evening, the Flying Pigs Amateur Radio Club International will be holding its monthly Run For The Bacon. This is a friendly, two hour QRP CW Sprint, which is open to ALL radio amateurs, will last from 9:00 - 11:00PM EDT (0200-0400 UTC Monday).

You may work stations once per band on 160, 80, 40, 20, 15 or 10 Meters. Suggested starting frequencies are 1.812, 3.562, 7.044, 14.062, 21.062, and 28.062 MHz.

The exchange is RST, S/P/C (State, Province, Country) and Flying Pigs membership number. If you're not a member of the Flying Pigs, and would like to be; then please cli

3883. Troubleshooting ATS3B - dj8ef

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-12-27 16:28:12 UTC
From: "Dr. György-Kiss, Franz"
Topic: 3883 Message: 3883

Hallo Forum Members,
My first Projekt ATS3A was not at all Problem. Very fine 4 band TRX!

I bilt my ATS3B (second Kit Serie Revisited Sept 16. 2007.) and I have
same troubles:
Check out and Calibration is OK!
Wire up with current limited supply. I had Modifikation down (22K
across the leads of C58!)
Reference Oscillator Frequency Calibration is OK!
Local Oscillator frequency trim with Oscilloscope OK
TP1 : 3,99V
The PA gates are at 0v. OK
All Band filter is OK, Rx input trimmers for the best Signal.
Power up : the Rig LED Diplay and Headfpones Tone OK in all Band's!

With my limited Supply and send with the paddle from 9V back to 4,5V and
ca. 180 mA! -but Powermeter : less Power! -and not 2,5 Watt!

With my unlimited (20A!) Supply LED display appears: "E"!!
-it is goes out with the Menu switch!

If I with one little screwdriver touch/contact the Programming Option
Pin RST, or Q5 collector or R43 the LED displays "E"!! It is Normal?
I had the IC Voltage tables in recive mode tested: OK!!!!

R 47 is 680Ohm OK!
R49 is 470 Ohm OK
R48 is 0,1 OHM OK!
R43 47 K OK!
D4 5,1 V Zener is OK!

This is very frustrating. Any suggestions would be greatly
appreciated. I'm sure it's something simple, but I don't NO where!

Wishing everyone happy new year 2009!

--- In AT_Sprint@yahoogroups.com, "Dr. György-Kiss, Franz" <gyokife@...> wrote:

Feri/Franz,

Many of us have had problems like what you describe.

One idea is to test your rig with a resistor in series with your power supply. This will limit the current. If you use a 12V supply, please try a resistor greater than 5 ohms and less than 7 ohms, in series with the positive lead.

The reduced voltage and current may allow you to tune up the rig without tripping the overcurrent sensor. If your ATS-3B runs OK with the series resistor, we will know that most of the functions are OK.

Please connect an accurate 50 ohm dummy load resistor to your ATS-3B rig for all tests. If your load is not 50 ohms, the rig may draw excess current and trigger the overcurrent sensor, which will cause it to show a letter "E" and stop normal operation.

I normally run my ATS-3B with 3 lithium ion cells, about 12.4V fully charged. I have a switch on the battery pack to add a 6.7 ohm resistor in series with the battery. This makes it easy to tune my tuner safely, and it prevents the overcurrent trip problem.

The ATS rigs need a good 50-ohm load. A good match is essential. Usually this means that some type of tuner with a match indicator is required.

If you operate your ATS-3B with a 12V power supply into a mismatch with SWR of 1.5 or greater, and the mismatch is due to an impedance lower than 50 ohms, the final mosfets will draw excess current, and the rig will trip out, and you will see a letter "E" when this happens. Usually this is very fast!

There are two parts to the answer for this problem:

1) Use a series resistor at first, to reduce the current and voltage

2) Use a matching circuit (tuner) adjusted for an accurate match.

Once the match is adjusted correctly, you may be able to run at full power.

Please make sure that your filter modules are correctly adjusted, since they may cause your rig to draw excess currect even with a 50 ohm load.

Please see the FILES section on this website. There you can find my paper that explains how to adjust the filter modules for maximum output and good efficiency.

You may also choose to increase the current limit slightly, as explained in my older post that Mike referenced.

I have been very pleased with this rig. It works well for portable operation and has enabled me to operate from amazing places in the mountains near here.

3886. ATS3A Blown MPU

Yahoo group: AT_Sprint (2002 — 2008)
Date: 2008-12-29 03:15:21 UTC
From: k2qpn
Topic: 3886 Message: 3886

Tonight my ATS3A quit working. No beeps only some hum. The 3.3V was zilch and the regulator was hot. The 3.3V was 6 ohms to ground. By lifting pin 2 of the MPS430 MPU the 3.3V returns. Looks like the MPU is blown.

Can I get a replacement with the stock code loaded? Can I just get a replacement and load the code myself? Is the stock code available? Is there a primer for the code load novice (like me)?

This on the same weekend that I sent my PFR3 chip back to Steve for reprogramming. I am QRPless.
